Abstract:	Using Cultural Psychology as a framework, this research measures and analyses heterogeneity in university teachers' conceptions of intelligence through unguided free-answer semi-structured interviews (N = 20). A new type of analysis, called Heterogeneity by Contradictions Analysis (HCA), was developed. First, a category system was created by making use of the interview data. Then, a series of possible contradictions among pairs of categories was pre-defined. Using these pre-defined contradictions, a systematic sampling of theoretical contradictions could be obtained from discourse. This sampling was then reviewed by the researcher in order to find and code real contradictions, which were later analyzed. 85% of participants presented at least some heterogeneity in their discourse by expressing an idea and its opposite in different parts of the interview. Content of discourse and context are analyzed in heterogeneity expression, which yields future implications for research, intervention, and teacher training.

Abstract

Using Cultural Psychology as a framework, this research measures and analyses heterogeneity in university teachers' conceptions of intelligence through unguided free-answer semi-structured interviews (N = 20). A new type of analysis, called Heterogeneity by Contradictions Analysis (HCA), was developed. First, a category system was created by making use of the interview data. Then, a series of possible contradictions among pairs of categories was pre-defined. Using these pre-defined contradictions, a systematic sampling of theoretical contradictions could be obtained from discourse. This sampling was then reviewed by the researcher in order to find and code real contradictions, which were later analyzed. 85% of participants presented at least some heterogeneity in their discourse by expressing an idea and its opposite in different parts of the interview. Content of discourse and context are analyzed in heterogeneity expression, which yields future implications for research, intervention, and teacher training.

Keywords: Teachers, Implicit Theories of Intelligence, Heterogeneity, Higher Education, Social Discourses

1
2
3 The complex concept of intelligence has been approached from different
4 epistemological and historical positions. Currently, there are competing and
5 complementary theories of intelligence (Garner, 1983; Goleman, 1995; Sternberg, 1985,
6 for some examples). Concepts which have been key in the study of such ability have
7 included inheritance, effort, expectations, context, training, culture, gender, and others
8 (Brinch & Galloway, 2012; Plomin & Von Stumm, 2018; Protzko, Aronson & Blair,
9 2013). All these theories are what are called explicit theories of intelligence, which are
10 developed within scientific research. Implicit theories, on the other hand, are personal
11 beliefs that are developed through personal and cultural experiences (Sternberg &
12 Davidson, 1986). These theories influence emotions, expectations, and behavior,
13 participating in the everyday life of everyone.

14
15 Carol Dweck (1986, 2000) defined two different and opposed conceptions on
16 intelligence: *the incremental theory of intelligence* postulates that intelligence can be
17 modified through continuous work and effort, while *the entity theory of intelligence*
18 argues that intelligence is innate and cannot be modified over the course of a person's
19 life. Adherence to one of those conceptions has been related to both learners' and
20 teachers' performance in several ways (Dweck, 1986; Renaud-Dube, Guay, Talbot,
21 Taylor & Koestner, 2015; Park, Gunderson, Tsukayama, Levine, & Beilock, 2016).

22
23 Teachers' theories of intelligence are related to their teaching practice. Teachers who
24 subscribed to an entity theory of intelligence were found to be more likely to have an
25 outcome-based teaching style (Park et al., 2016) and are more likely to react to students'
26 failures by consoling them for their low natural capacity (Rattan, Good & Dweck,
27 2012). They engage in ineffective strategies to try to motivate them, thus in fact
28 lowering both their motivation and self-efficacy. Patterson, Kravchenko, Chen-Bouck,
29 and Kelley (2016) also found that teachers more oriented towards entity theories of

1
2
3 intelligence feel less responsible for the academic achievements of their students.

4
5 Teachers who subscribed to an incremental theory, on the other hand, present higher
6
7 teacher efficacy (Stroscher, 2003), which is related to greater persistence when dealing
8
9 with struggling students (Gigson & Dembo, 1984), better academic outcomes (Katz &
10
11 Stupel, 2016), and less teaching-related stress (Senler, 2016).
12
13
14

15
16 These intelligence beliefs have been studied as decontextualized conceptions that
17
18 would operate in all activities the person is involved in in a homogeneous manner (see,
19
20 for example, Stroscher, 2003). Several times, it has been studied as two poles of the same
21
22 concept, as a continuum, negating the diversity of arguments and opinions that can co-
23
24 exist within the same person, just for the sake of simplicity or generalization and
25
26 measuring it as a unique number (Park et al., 2016 for example).
27
28
29

30
31 This type of research collides with the perspective developed by Cultural Psychology
32
33 (Cole, 1996; Cole & Packer, 2019; Cubero, Contreras, and Cubero, 2016; Cubero,
34
35 Rubio, and Barragán, 2005; Tulviste, 1982, 1989; Valsiner, 2007; Wertsch, 1985,
36
37 1989). From this framework, psychological processes have a cultural-historical genesis,
38
39 where culture is understood as a set of cultural practices or activity settings a person is
40
41 involved with. These practices are mediated by the use of symbols, signs, and tools that
42
43 transform talk, thought, and human action (Vygotsky, 1978; Wertsch, 1989). This
44
45 transformation process from social activities (interpsychological level) to
46
47 intrapsychological phenomena is called internalization (Wertsch, 1985).
48
49
50

51
52 Activity settings are comprised by a set of assumptions about appropriate roles,
53
54 goals, and means used by participants in that setting (Wertsch, 1985, p. 212). Cognition
55
56 is, then, functionally related to those activity settings and can vary across each of them.
57
58 Development is viewed as a process of situated different constructions of cognition
59
60

1
2
3 which depends extensively on the demands and activities related to each specific
4 context. It is not a general idea or variable that affects every context, as it seems
5 implicitly thought by research, but rather a set of different ideas associated to (and
6 created within) each context.
7
8
9
10
11
12

13 Mediated actions by tools, specifically language, are the link between culture and
14 individuals. According to our perspective, social discourses have a sociohistorical
15 development and are culturally situated. As different social discourses exist within
16 cultures, a wide range of possibilities is present for the construction of different
17 semiotic tools that are functionally related to specific activity settings (Santamaria &
18 Martinez, 2005), such as those related to incremental or entity conceptions of
19 intelligence. This leads to variability or heterogeneity of conceptions within individuals,
20 which is explained in terms of the different activity settings in which they participate.
21 According to Zittoun & Gillespie (2015), culture is heterogeneous and fragmented, so
22 we could say that the experiences in different activity settings will be also
23 heterogeneous and fragmented.
24
25
26
27
28
29
30
31
32
33
34
35
36
37
38

39 As previously stated, research related to intelligence conceptions does not consider
40 the differential development of teachers and learners across different activity settings
41 nor the variability or heterogeneity of conceptions such individuals show in those
42 contexts. Measuring by general decontextualized statements using Likert-like scales
43 cannot grasp the diversity of verbal thinking a person can develop across their lifetime.
44 Several papers regarding conceptions of intelligence point to this diversity too. In a
45 series of studies done by Leith et al. (2014), researchers tested change of implicit
46 theories in participants in several experimental conditions. They found that people
47 modified their implicit theories in accordance with specific aims and social situations.
48 When they encountered a situation that threatened their self-concept or that of
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3 significant others, they strategically hold a more incremental view of change to protect
4 either themselves or others. Poon & Koehler (2006) demonstrated that people have
5 access to both implicit theories of change and stability. The participants in their study
6 explained a series of cases (for instance, the story of an individual who showed marked
7 personality stability through life, or marked change) giving explanations and examples
8 supporting both types of theories, depending on what the case had primed.
9

10
11 As previously stated, we believe such discourses are functionally related to different
12 contexts. We think there is no need to explicitly manipulate participants in order to
13 make heterogeneity appear, as they would occur naturally by simply introducing
14 different semiotic contexts. In a previous study we analyzed conceptions of intelligence
15 among university teachers using an unguided interview in which participants
16 commented on different everyday cases, or vignettes, regarding several aspects of
17 intelligence (Matías-García, 2016). We decided to analyze heterogeneity in their
18 descriptions through the study of contradictions in their discourse. Our goals are the
19 following:
20
21

- 22 - To ascertain the heterogeneous nature of conceptions of intelligence.
- 23 - To determine if heterogeneity varies across different types of concepts and
24 situations, and how does it so.

25 26 27 28 29 30 31 32 33 34 35 36 37 38 39 40 41 42 43 44 45 46 47 48 49 50 51 52 53 54 55 56 57 58 59 60

Method

Participants

Participants were selected according to three criteria in order to explore the maximum variety of views we could find: gender, field of knowledge in which they lecture, and years of teaching experience. The sample comprised 20 university teaching staff (10 men and 10 women) from the University of Seville, all of them from Spain, with a mean age of 42.7 and a standard deviation of 11. Four participants were selected

1
2
3 from each field of knowledge, according to the category system in place at the
4
5 university in question (Table 1). The selection process ensured that half the participants
6
7 had less than 15 years' teaching experience at the university ($M = 6.60$, $SD = 4.42$), and
8
9 the other half more than 15 years' experience ($M = 24.3$, $SD = 10.1$). The only inclusion
10
11 criterion used was that university teachers had to be currently lecturing at the university,
12
13 regardless of their position or training.
14
15

16 17 **Instruments and Materials**

18
19
20 A semi-structured interview was designed, called "Views on intelligence within the
21
22 educational field" (VIEF) (Appendix A) (Agudelo, 2015, Camas, Caro, Matías-García
23
24 & Cubero, 2015). The instrument comprises 24 cases, 2 for each of the 12 variables
25
26 considered. These cases are so called vignettes in some approaches in educational and
27
28 social research (ÅKERLIND, 2005; Kandemir & Budd, 2018). The variables refer to
29
30 relevant dimensions in which the view on intelligence could be expressed and
31
32 contextualized. The variables taken into consideration were: Control, Heredity, Effort,
33
34 Culture, Training, Critical Period, Context, Expectations, Associated Qualities, People,
35
36 Gender, and Diversity of Intelligence. All those variables have been found relevant in
37
38 scientific study of intelligence (Brinch & Galloway, 2012; Plomin & Von Stumm, 2018;
39
40 Protzko, Aronson & Blair, 2013). They are also relevant in the everyday use of the
41
42 concept in different contexts, such as media, family, school, etc. The average duration
43
44 of the interviews was 31 minutes.
45
46
47
48
49

50
51 Authenticity in the interview is achieved by naming neutral authors and phrasing the
52
53 statements in a simple way - as commonly uttered statements. The vignettes presented
54
55 followed the same structure: "A source says + a statement related to intelligence". In
56
57 order to avoid making it difficult for participants to contradict the statement, sources
58
59 were never experts in the issue being analyzed. Examples of sources include "a blog",
60

1
2
3 "a politician", "a mother", and "a popular saying". Sources were never repeated, and
4
5 both sexes were equally represented within a wide variety of everyday contexts. All
6
7 statements contained the word "intelligence" or "intelligent", in order to elicit responses
8
9 related to this concept. Finally, all statements were phrased as something that could be
10
11 said by a normal person, with no specific concepts or terms from psychological
12
13 literature being used. The aim was to ensure that they were as similar as possible to
14
15 statements and assertions that participants would have already heard in their everyday
16
17 social interactions. Participants are asked to give their opinion about each vignette.
18
19

20
21 The instrument was tested with two university teachers from the Psychology Faculty
22
23 and other adults from outside the teaching field. Following the pilot test, the initial
24
25 position of two items and the phrasing of one question were modified. All interviews
26
27 were digitally recorded. The Atlas.ti program was used for the qualitative analysis
28
29 directly onto the recordings, without transcription.
30
31

32 33 **Procedure**

34
35 In order to establish and select the sample group, potential participants were
36
37 contacted through their university email addresses. All addresses were taken from the
38
39 University of Seville website. Participants agreed to collaborate in the study after being
40
41 informed of the objectives and the content of the interview in global terms, situating the
42
43 contents of the interview on educational topics; they did not receive any incentives. All
44
45 the interviews were held in the teachers' own offices in Spanish, as it was their mother
46
47 language, and lasted as much as one hour. All participants were interviewed by the same
48
49 researcher.
50
51
52
53

54
55 Participants were asked what they thought about each vignette of the interview. In a
56
57 few situations, if the response was too short or ambiguous in the interviewer's opinion,
58
59
60

1
2
3 participants were asked if they had anything else to add. They were encouraged to
4
5 express all they wanted.
6
7

8 **Data analysis**

9
10
11 A category system used was used as a tool for coding the participants' descriptions
12 and explanations during the interview. The utterances were segmented and analyzed
13 considering the *unit of meaning* as the unit of analysis. A unit of meaning is a unit of
14 discourse that contains an idea or a theme, which can or not concur with the syntactic
15 unit of the sentence or sentences being presented. A new unit starts in discourse when
16 there is a change in the theme of the content being expressed, i.e. that which is being
17 spoken about. A sentence can contain more than one unit of meaning.
18
19
20
21
22
23
24
25
26
27

28 The category system presents 116 units of meaning related to intelligence, organized in
29 18 different topics. These topics were: Effort, Genetic Influence, Development in Non-
30 Specific Terms, Global Environment, Formal Education, Culture, Activities, Teacher
31 Influence, Parental Influence, Developmental Characteristics, Motivational and
32 Emotional Influence, Others' Expectations Influence, Own Expectations Influence,
33 Other Personal Characteristics Influence, Characteristics Associated to Intelligent
34 People, Gender, Presence of Intelligence in Activities Outside Academic Fields, and
35 Social and Emotional Intelligence. Most categories in this system were developed
36 considering the explicit expression by a participant of the influence or no influence on
37 intelligence of a certain activity, personal characteristic, or contextual factor. Some
38 examples of categories can be *Formal education improves intelligence* or *Formal*
39 *education does not improve intelligence*. Kappa Index was calculated as an inter-rater
40 reliability measure of the categorization, obtaining a value of 0.861.

1
2
3 A specific type of analysis called Heterogeneity by Contradictions Analysis (HCA)
4 was developed. Using the units of meaning of our system as base, 165 categories of
5 contradictions were pre-defined by the researcher. Each contradiction was defined by
6 two contradictory units of meaning. Two types of contradictions were categorized by
7 taking into account the type of unit of meaning used. If the contradiction was presented
8 between two categories referring to the same idea but opposed in the direction of the
9 relationship with intelligence (for instance, a contradiction between the categories *Effort*
10 *improves intelligence* vs *Effort does not improve intelligence*), the contradiction was
11 called *Direct Contradiction*. In this type of contradiction, the participant explicitly
12 expresses exactly the opposite to something he/she previously said. The other type of
13 contradiction involves two categories that do not refer to the same idea but should not
14 appear at the same time during the interview by terms of common logic. One example
15 of this would be a contradiction between the categories *Effort improves intelligence* and
16 *Intelligence does not change with age*. The former category expresses how putting an
17 effort in the things you do is important for the development of intelligence, while the
18 latter says that intelligence cannot be modified through your lifetime. However, if it
19 can't be developed during your life, it couldn't be developed through effort nor in any
20 other way. This kind of contradiction related to coherence was called *Coherence*
21 *Contradiction*.

22
23

38
39
40
41
42
43
44
45
46
47
48 This relation system of units of meaning was created as a tool for the systematic
49 sampling of verbal contradictions in the interview. For filtering false positive findings,
50 all pairs of contradicted categories were listened to again by the researcher for
51
52
53
54
55
56
57
58
59
60
ascertaining the appearance of real contradictions between categories. Each possible
contradiction found by the system was labelled as "Incoherent" (The participant says
opposite or incoherent explicit verbal expressions in terms of the proposed relation),

1
2
3 “Uncertain” (There is no sufficient information to know if there is an explicit real
4 contradiction), or “Not Incoherent” (The sentences are expressed in a way that they do
5 not present an explicit contradiction). Only those labelled as “Incoherent” constitutes
6 the corpus of data of this study. Figure 1 summarizes the procedure followed by HCA.
7
8
9
10
11
12

13 Final contradictions were organized in 21 types of contradictions depending of
14 content (Table 2). These types of contradictions could include either direct or coherence
15 contradictions, or both.
16
17
18
19
20

21 Results

22
23
24 By applying HCA to data, we found 412 possible cases of contradictions. After the
25 researcher’s filtering of data and second coding, 311 contradictions were labelled as
26 “incoherent”, 37 as “uncertain”, and 64 as “not incoherent”. Those labelled as
27 incoherent were analyzed.
28
29
30
31
32
33

34 For illustration purposes, we present the transcription of two contradictions identified
35 by our procedure and labelled as “incoherent”.
36
37
38

39 In case of vignette 1, “*A boy in his school says that his friend is very intelligent*
40 *because she puts a lot of effort in everything*”, the Physics Studies participant stated:
41
42
43
44

45 “Well, being intelligent and effort don’t have to be correlated. Being intelligent and
46 putting an effort are different things. Intelligent people will have to put an effort, while
47 those who put an effort will have to acquire knowledge. Apart from that, one thing does
48 not imply the other one.”
49
50
51
52
53

54 Categories codified: *Effort does not improve intelligence; Learning new knowledge*
55 *or new abilities do not improve intelligence.*
56
57
58
59
60

1
2
3 However, in vignette 3, “*My neighbor says that her daughter of 4 years-old is not so*
4 *intelligent, but as she is going to start infant school, she thinks her daughter will*
5 *improve*”, the same participant explained:
6
7

8
9
10 “(...) Going to school creates intelligence... well, yeah, it provides them with
11 knowledge, with learning how to behave... it helps them in many things and it teaches
12 them.”
13
14
15

16
17
18 Categories codified: *Infancy is an important period for the development of*
19 *intelligence; Formal education improves intelligence; Learning new knowledge or new*
20 *abilities improves intelligence.*
21
22
23

24
25
26 By our pre-defined system of contradictions, we found a possible contradiction
27 between *Learning new knowledge or new abilities do not improve intelligence* and
28 *Learning new knowledge or new abilities improve intelligence*. In the first case, the
29 participant doesn't find any relationship between gaining knowledge (through effort)
30 and intelligence. For her, putting an effort and gaining knowledge and being intelligent
31 are both different and non-related things. However, in the second case, in order to
32 defend the development of intelligence by the school, she mentioned its role in
33 providing knowledge. She, then, expressed a link between learning and the development
34 of intelligence. This was codified as incoherent, and, then, a direct contradiction in the
35 *Influence of Learning New Knowledge or New Abilities in Intelligence Development*
36 was found.
37
38
39
40
41
42
43
44
45
46
47
48
49
50

51
52 Another example is that of the Journalism Studies participant, who affirmed in
53 vignette 2, “*On television, an educational game for improving intelligence in boys and*
54 *girls, which consists of doing certain activities, has being announced*”, the following:
55
56
57
58
59
60

1
2
3
4 “Well, I would buy it for my children, of course. You don’t lose anything for trying.
5 I guess it might enhance certain cognitive abilities, so it would improve... not only
6 intelligence, but also their own abilities. I mean, it may also improve their linguistic or
7
8 math areas”.

9
10
11
12
13 Category codified: *Instruments developed for improving intelligence (games,*
14
15 *intervention programs, tv shows) can improve intelligence.*

16
17
18 However, in vignette 23, “*I have read in a blog that, as scientist says, maturation*
19 *ends in adolescence; intelligence cannot be improved beyond that moment*”, the same
20
21 participant answered:
22
23

24
25
26 “I don’t believe... intelligence can grow as you want it to. I mean, you are born with
27 a particular intelligence and you can’t go improving it. But you can exploit a lot your
28 other abilities: you can improve your memory, your emotions, your creative areas... by
29 working, by making an effort, you can develop your linguistic or mathematical areas.
30 Everything you work... you are gonna keep improving your knowledge and your field
31 of action. But your intelligence, I don’t think it is like a chewing gum, which you can
32 stretch”
33
34
35
36
37
38
39
40
41
42

43 Categories codified: *Intelligence does not change along the vital cycle; Genetics*
44 *determine a certain level of intelligence; Intelligence (in general, explicitly said) cannot*
45 *be changed; You cannot do anything (in general) to improve your own intelligence;*
46 *Effort does not improve intelligence; Learning new knowledge or new abilities does not*
47 *improve intelligence; Emotion or motivation is not related to intelligence development.*
48
49
50
51
52
53
54

55 In this case, by our pre-defined system of contradictions we found a possible
56 contradiction between *Instruments developed for improving intelligence (games,*
57 *intervention programs, tv shows) can improve intelligence* and *Intelligence (in general,*
58
59
60

1
2
3 *explicitly said) cannot be changed*, among others. In the first case, the participant finds
4 a relation between an instrument for improving intelligence, an educational game, and
5 the possibility of intelligence improvement. However, much later in the interview, the
6 participant expressed that intelligence cannot be improved in any way during your life,
7 making it a contradiction. The participant explicit and specifically informs of the
8 improvement in intelligence by a particular activity (an educational game), and not of
9 the possibility (in general) of improving intelligence (which is what she negated later),
10 so the contradiction was categorized as a coherence contradiction in *Use of Instruments*
11 *Developed for Improving Intelligence Influence*. If she had explicitly negated the effect
12 of such instruments, that would have made a direct contradiction of the same category.
13
14
15
16
17
18
19
20
21
22
23
24
25

26
27 Following this system, the basic unit of the measure of a contradiction cannot be the
28 frequency of contradictions in terms of the category system. Since the category system
29 has been developed for extracting all possible fragments of meaning, there may be
30 overlaps in the counting of contradictions by considering different views of analysis.
31 For instance, in the last example, we have said there is a contradiction between
32 *Instruments developed for improving intelligence (games, intervention programs, tv*
33 *shows) can improve intelligence* and *Intelligence (in general, explicitly said) cannot be*
34 *changed*, but there is also between the first and two other categories: *Intelligence does*
35 *not change along the vital cycle* and *You cannot do anything (in general) to improve*
36 *your own intelligence*. However, counting three different contradictions because of the
37 characteristics of our tool would overestimate the number of contradictions. Also, we
38 would have too many different types of contradictions (considering each dyad) and
39 content analysis would be difficult. For solving these problems, we calculated the
40 percentages of participants that have expressed a category which has been contradicted
41 elsewhere in the interview by another category, independently of how many times. This
42

1
2
3 helps us simplify and analyze contradictions regarding content, by focusing on one
4 category of the two (or more) that makes a contradiction. Thus, regarding the previous
5 example, we would consider only one coherence contradiction in vignette 2 in relation
6 to the use of instruments. This helps us understand how heterogeneous the concept of
7 improvement of intelligence is by using instruments designed for that purpose.
8
9
10
11
12
13

14 15 General Data

16
17
18 Table 2 shows percentages of heterogeneity related to the whole interview. The
19 percentage of contradicted participants is calculated by dividing the number of
20 participants who have made at least one contradiction related to that concept by the
21 number of participants who have spoken about that concept. As participants were free to
22 speak their minds, not everyone spoke about all studied contents.
23
24
25
26
27
28
29

30
31 Data shows differences in the degree of heterogeneity related to each concept,
32 ranging from 7% to 73%. Several concepts show high degree of contradiction, such as
33 the influence on intelligence of learning new knowledge or abilities, students' effort,
34 formal education, and the means and culture of a country (see Table 2). The last
35 category of the table shows that an 85% of the total number of participants present at
36 least one contradiction in their interview in their arguments related to influence on
37 intelligence and 89% in those related to no influence. See table 2 for details about all
38 categories.
39

45
46
47
48

49 Cases data, context-related differences

50
51
52
53 Most salient data will be explained. There is a high heterogeneity in the concept the
54 improvement of intelligence by effort. However, almost all of its heterogeneity
55 concentrates in the first case (80% of participants who have made that contradiction),
56 where participants negated effort's influence, while saying the opposite later in many
57
58
59
60

1
2
3 different cases which were disseminated across the interview in a homogeneous manner.

60
intelligences. This leads us to believe that our participants do not directly link situations
in which a learner puts a lot of effort with the improvement of intelligence; they rather
include the concept of effort when they are speaking about other concepts related to
intelligence, as an extra argument to the idea of change and improvement, as another
way of improving it.

A similar case is that of the relation between learning and intelligence, which was
found the most heterogeneous concept in our participants. Both explanations about the
relation and no relation are homogeneously disseminated across the interview, but
vignette 16, “*A child says he feels intelligent after having learnt to do a new school*
task”, which directly links together these two concepts, concentrated most of its
heterogeneity. 81% of participants who made that contradiction were found in the
negation side (also, 9% on the affirmation side). In fact, sometimes participants even
laughed at the item, saying that would be something only a child would say. Learning is
also used as an extra-argument for supporting other pro-change ideas, but when a child
learns something new, they do not seem to identify an improvement in the child’s
intelligence. The first example we previously showed to illustrate direct contradictions
is also an example of this.

Another interesting context-related data are those of vignettes 11, “*A politician says*
African children who live in impoverished environments will never become as
intelligent as children who live in developed countries”, and 17, “*In the radio, it has*
been said that Finnish children are more intelligent because they live in a more
developed society”. Vignette 11 concentrated all contradictions related to the influence

1
2
3 of means and culture of a country, while case 17 concentrated all contradiction related
4 to no influence on intelligence of that same category. In this case, some participants'
5 explanations were in terms of the no influence of the educative system, which explained
6 the differences between countries but had nothing to do with intelligence. Sometimes,
7 this led to new contradictions related to formal education for those participants (50%).
8
9

10 11 12 13 14 15 Intra-vignette contradictions

16
17 Sometimes, participants made a whole contradiction during their answer to a
18 vignette, meaning that they explicitly expressed a concept and its opposite during their
19 own continuous discourse, without changing vignettes. We found 5 of such cases during
20 our interviews. In those cases, these participants expressed one view first. However,
21 during their own descriptions, they dynamically self-included concepts, ideas, and
22 arguments that made them shift their views. Finally, they ended up telling the opposite
23 argument. It seemed in most cases they did not even realize. Some examples:
24
25
26
27
28
29
30
31

32
33 Optometry Studies participant, in vignette 5, *In general, people think intelligent*
34 *people have many friends*, answered:
35
36

37
38 "I think it's just the opposite, I think it's just the opposite... Many times, based on the
39 stereotype we have of intelligent people, we have the stereotype of a shut-in person, an
40 adult who is locked in their work and many times, when tv programs shows the
41 prototype of intelligent children, they also show a prototype of child who is kind of
42 isolated from the rest, so I wouldn't agree considering the stereotype... But that's the
43 stereotype they propose, I don't think they have to have more nor less friends for being
44 intelligent."
45
46
47
48
49
50
51
52

53
54 First, he positioned himself in the stereotype of introvert children and obsessed adults
55 who have no friends, but in the end, he negated the stereotypes and claimed there was
56
57
58
59
60

1
2
3 no relation between the number of friends and intelligence. A direct contradiction in the
4
5 *Linkage Between Sociability and Intelligence* was, therefore, found.

6
7 Pharmacy Studies participant, in vignette 2, “*In television, an educational game for*
8 *improving intelligence in boys and girls by making certain activities it is being*
9 *announced*”, answered:

10
11
12 “Well, I think there are activities you can do to train memory, indeed. In fact, there
13
14 are lots of games for children about colors, of picking cards up... Did you say for
15
16 training intelligence? I think intelligence can’t be trained, can it? Well, you can train
17
18 memory and become more intelligent by that, but... I don’t know.”

19
20 She said intelligence couldn’t be trained, but later, she said you could improve
21
22 intelligence by training memory. It was coded as a coherence contradiction in the *Use of*
23
24 *Instruments Developed for Improving Intelligence Influence*.

25 26 27 28 29 30 31 **Discussion**

32
33 Data shows there exists heterogeneity in conceptions of intelligence among
34
35 participants. Its appearance is high and its degree ranges from 7% to 73% of responses
36
37 depending of the content being analyzed. Most of research assesses implicit theories of
38
39 intelligence as a continuum, using instruments like Likert scales and other that, by
40
41 researcher definition, make them look like that. However, as our study has found,
42
43 participants’ theories do not form a continuum, but a set of different specific
44
45 constructions of knowledge in discourse. Radical changes in the participants’
46
47 descriptions can be made depending on semiotic context (Wertsch, 1985), such as
48
49 saying both that learning improves intelligence and that there is no relation between the
50
51 two. This differential way of speaking would certainly impact all variables that have
52
53 been linked to implicit theories of intelligence, as people dynamically change their
54
55 views (Leith et al., 2014) even without explicit and direct manipulation. A more
56
57
58
59
60

1
2
3 contextualized assessment appears to be necessary in order to better grasp these
4
5 dynamic elements, so we can study how they relate to effects in other variables about
6
7 learning.
8
9

10 According to Cultural Psychology (Cole, 1996; Cole & Packer, 2019; Cubero,
11
12 Contreras, and Cubero, 2016; Cubero, Rubio, and Barragán, 2005; Tulviste, 1982, 1989;
13
14 Valsiner, 2007, 2014; Wertsch, 1985, 1989), we assume participants, during their lives,
15
16 have participated in different activity settings that presented different goals, roles, and
17
18 use of words. By means of that participation, they would have acquired and constructed
19
20 different knowledge and semiotic tools that were functionally related to such activity
21
22 settings (Santamaria & Martinez, 2005). As different social discourses exist within our
23
24 culture regarding intelligence, different views are developed. When we begin our
25
26 interview, we create a context of discourse similar to some activity setting they have
27
28 experienced, making it possible to express some meanings developed within such
29
30 activity setting. However, as more vignettes are introduced, elements of different
31
32 discursive contexts are included, modifying the activity setting and making participants
33
34 express different descriptions, giving rise to heterogeneity expression. This has been
35
36 previously found in other studies (Cubero et al., 2005). Sometimes, the change in
37
38 activity settings was even made by the participant's own discourse, as the appearance of
39
40 intra-vignette contradictions suggests. They themselves included new concepts or ideas
41
42 in their answers that led them to an argument or explanation developed within another
43
44 discursive context, making them express contradictory views. For instance, the
45
46 Pharmacy Studies participant began by commenting on the existence of educational
47
48 games developed to improve memory, but that intelligence could not be improved.
49
50 Then, she came to the realization that intelligence and memory are related and,
51
52 therefore, concluded intelligence could be developed through memory. It was her
53
54
55
56
57
58
59
60

1
2
3 inclusion of the concept of memory, contextualized in educational games for children,
4
5 what led her to shift her description of intelligence. This can be seen as a way of
6
7 reconstructing her conceptions, by metacognitively reflecting on her explicit
8
9 contradictions (Efklides, 2014). However, as her interview continued (by presenting
10
11 new cases or vignettes that were discursively related to different activity settings), she
12
13 immediately shifted back to entity descriptions.
14
15

16
17 We found different degrees of coherence and heterogeneity across different types of
18
19 content. We could assume that different degrees of heterogeneity would be found
20
21 considering the different appearance of such arguments in culture as social discourses
22
23 (Santamaria & Martinez, 2005). Arguments are dependent on content, and society
24
25 agrees more about certain topics, while other topics show a range of different
26
27 possibilities of positioning. As more different social discourses arise from different
28
29 activity settings, more possibilities of contradiction arise, and different degrees of
30
31 heterogeneity should be found.
32
33

34
35 Our study also found that although most participants agree in the influence of effort
36
37 (70%) and learning (75%) in the improvement of intelligence, they don't do so when
38
39 those same variables are the main topic of discussion, leading to several direct
40
41 contradictions (44% and 69% of contradicted participants, respectively). When asked
42
43 about a child who is putting a lot of effort or who is learning and making progresses,
44
45 they do not identify a possible improvement in intelligence. Conceptions of intelligence
46
47 of teachers influence students' conceptions of intelligence and are related to their own
48
49 teaching practice: if teachers express a different theory of intelligence when finding a
50
51 child of these characteristics, they may act differently, using different social discourses
52
53 to console them and putting different resources into action than in other circumstances
54
55 (Park et al., 2016; Rattan, Good & Dweck, 2012). Perhaps, if we train teachers to
56
57
58
59
60

1
2
3 identify change in intelligence in students who are learning and putting an effort to
4
5 improve, we might be able to give them tools to change or maintain their conception of
6
7 intelligence and, by doing so, affect their teaching methods towards them.
8
9

10 It is worth to note that only three participants had zero contradictions in our
11
12 interview: the Psychology, Primary Education, and English Studies participants. The
13
14 Psychology and Primary Education participants had a curricula which specifically
15
16 meant the study of the concept of intelligence from different theories and current
17
18 scientific knowledge. English Studies participant said during the interview she had
19
20 worked with intelligence tests and on language and intelligence matters. This might lead
21
22 to an expert effect of the internal coherence of concepts as the explicit knowledge has
23
24 been part of activity settings in their experience. Expert studies have found that experts
25
26 have richer and more coherent knowledge about their academic domains (Carey &
27
28 Spelke, 1994; Chi, Hutchinson & Robin, 1989; Chi, Slotta & De Leeuw, 1994),
29
30 perceive more meaningful patterns, represent problems in at a deeper and principled
31
32 level, have strong self-monitoring skills, and base their actions on theories (while
33
34 novices show a more data-driven and opportunistic planning) (Glaser and Chi, 1988;
35
36 Hsu, Lin, Wu, Lee, & Hwang, 2012; Kuchinke, 1996). In accordance with the previous
37
38 research, we think university teaching staff, as their scientific experience increase, the
39
40 different activity settings begin to share a common and coherent structure of knowledge,
41
42 which might lead to less heterogeneity and more coherence in their implicit knowledge.
43
44 Nevertheless, more research should be done in order to confirm such hypothesis, since
45
46 in our study such level of involvement has not been systematically controlled.
47
48
49
50
51
52

53 Finally, future research should also be done to better characterize heterogeneity and
54
55 its influence on learning environments. The descriptive nature of this paper helps us
56
57 understand how these conceptions are, but studies that link coherence/heterogeneity
58
59
60

1
2
3 with actual consequences in learning environments, from both the perspective of
4
5 learners and teachers, should be interesting in order to better comprehend conceptions
6
7 of intelligence.
8
9

10 **Conclusions**

11
12
13
14 According to Vygotsky's (1978) approach, there is no single type of development
15
16 relevant to the explanation of human intellectual functioning, but different types of
17
18 development or genetic levels, which are the phylogenetic, sociogenetic, ontogenetic,
19
20 and microgenetic levels (Cubero, 2005). Although Vygotsky made no direct reference
21
22 to this last level, some authors have indicated that it can be found in his work (Kozulin,
23
24 1990; Wertsch, 1985). Through our study, we are able to describe the interaction of the
25
26 last three domains, which we think is relevant to point out. First, in terms of
27
28 sociogenesis, this study is framed and refers to the broader sociocultural environment,
29
30 which exerts an influence on the understanding of intelligence within social groups.
31
32

33 This aspect of sociohistorical nature is materialized in the form of social discourses
34
35 elaborated in the culture and institutional activity settings. Secondly, the ontogenetic
36
37 level is manifested in the experiential and activity contexts in which each person
38
39 participates throughout his/her life span. Third and last, in the microgenetic level, we
40
41 find specific reflections prompted by the vignettes and discursively generated at the
42
43 specific moment of the interview. Taking all three levels together, we can say that,
44
45 during the interview, the participants develop discourses, weaving in specific personal
46
47 life course experiences which in turn are influenced by the sociocultural environment.
48
49 In this process, the participants construct their personal web of understanding of
50
51 intelligence in which they can hold contradictory views – without being aware of it.
52
53
54
55
56
57
58
59
60

1
2
3 Conceptions of intelligence are important for many different aspects of teaching and
4 learning. However, they are more complex than most research think they are. Through
5 an unguided free-response interview consisting of vignettes, we have found evidence
6 that support the heterogeneous nature of conceptions of intelligence, and that coherence
7 and perception of intelligence could be trained, as 3 participants showed. We have
8 developed a new technique which elicits implicit assumptions and highlights the
9 heterogeneity of discourse surrounding the concept of intelligence. This technique could
10 also be applied to other “sensitive” areas, such as identities, migration, feminism, and so
11 on.
12
13
14
15
16
17
18
19
20
21
22

23
24 This type of research yields more context-specific data and more precise
25 measurements of the way participants interact with their environments. The differential
26 usage of ideas about the influence of learning and effort on intelligence is a suitable
27 example of these context-specific measurements. This is in turn important, as
28 conceptions of intelligence influences teaching practices, and students’ learning
29 outcomes and well-being.
30
31
32
33
34
35
36
37

38
39 However, our conclusions are not only important for this population, but also for the
40 way beliefs should be understood. Conceptions are contextually and discursively
41 influenced, making them dynamic and modifiable, so research should bear that in mind
42 in other studies using other different populations. Taking Cultural Psychology as a
43 framework for studying implicit theories or conceptions, we can better grasp beliefs in
44 their complexity.
45

Table 2

Data on Contradictions. Influence and No Influence on Intelligence.

		Total % of Contradicted Participants	
		Influence	No Influence
Influence of Effort in Intelligence Development	Direct contradictions	36%	45%
	Coherence contradictions	29%	-
	Total contradictions	43%	-
Non-Specific Development of Intelligence Environment Influence in General in Intelligence Development	Direct contradictions	18%	40%
	Coherence contradictions	29%	-
	Total contradictions	23%	43%
Formal Education Influence in Intelligence Development	Coherence contradictions	38%	-
	Total contradictions	46%	-
	Direct contradictions	25%	30%
Influence of the Means and Culture of a Country or Context	Coherence contradictions	33%	-
	Total Contrad	33%	-
	Direct contradictions	14%	25%
Influence of Actions (Non-Specific) in Intelligence Development	Coherence contradictions	7%	-
	Total contradictions	21%	-
	Direct contradictions	73%	69%
Influence of Learning New Knowledge or New Abilities In Intelligence Development	Coherence contradictions	33%	-
	Total contradictions	73%	-
	Coherence contradictions	14%	-
Influence of Participation in Different Types of Activities in Intelligence Development	Coherence contradictions	33%	-
	Coherence contradictions	33%	-
Different Kind of Intelligences are Developed in Relation to the Type of Activity that is Done	Coherence contradictions	33%	-
	Coherence contradictions	7%	33%
Use of Instruments Developed for Improving Intelligence Influence	Coherence contradictions	36%	-

	Total contradictions	36%	-
Influence of Teachers in Intelligence Development	Coherence contradictions	62%	-
	Direct contradictions	7%	17%
Influence of Fathers and Mothers in Intelligence Development	Coherence contradictions	50%	-
	Total contradictions	50%	-
Possibilities of Development of Intelligence Along the Whole Vital Cycle	Coherence contradictions	8%	-
Influence of Motivation and Emotions In Intelligence Development	Coherence contradictions	14%	-
Others' Expectations Influence in Intelligence Development	Coherence contradictions	17%	-
	Direct contradictions	11%	13%
Verbal Positive Reinforcement Influence in Intelligence Development	Coherence contradictions	44%	-
	Total contradictions	44%	-
Influence of Your Own Expectations in Intelligence Development	Coherence contradictions	20%	-
Linkage Between Sociability and Intelligence	Direct contradictions	11%	13%
Arguments about Genetic Influence in Intelligence Development	Direct contradictions	11%	50%
Influence of Personal Experiences In Intelligence Development	Coherence contradictions	75%	-
Social or Emotional Intelligence Development	Direct contradictions	20%	14%
Arguments About the Modifiability of Intelligence	Total contradictions	85%	89%

Appendix A

PROJECT: "CONCEPTIONS OF INTELLIGENCE IN THE EDUCATIONAL FIELD.
UNIVERSITY TEACHER'S IMPLICIT THEORIES" (VIEF)

Age: ___ Sex: _____ Field of Knowledge: _____

Teaching experience: _____ Date: _____

Interviewer: _____

We are doing a research about different educational topics. Now, we are going to present you a series of hypothetical cases in which we will ask your opinion about what is being stated in them. We thank your collaboration and your help in the building of knowledge. Once you are ready, we can start the interview.

1. A boy in his school says that his friend is very intelligent because she puts a lot of effort in everything. (Effort Dimension)
2. On television, an educational game for improving intelligence in boys and girls, which consists of doing certain activities, has being announced. (Training Dimension).
3. My neighbor says that her daughter of 4 years-old is not so intelligent, but as she is going to start infant school, she thinks her daughter will improve. (Context Dimension)
4. A collection of proverbs says that you can't be made intelligent; you need to be born intelligent. (Heredity Dimension)
5. In general, people think intelligent people have many friends. (Associated Qualities Dimension)
6. Praising children by acknowledging their brilliance can make their intelligence to be improved. (Expectations Dimension)
7. My cousin, who works in a motorcycle workshop, says he is very intelligent because he is capable of assembling and disassembling a motorcycle in an afternoon. (Diversity of Intelligence Dimension)
8. I have always been told that if you set it as a goal, you can become more intelligent. (Control Dimension)
9. In a Youtube video, it was said that people are born with a certain intelligence that can be improved or made worse depending on what happens to them during their infancy (Critical Period Dimension)

10. I have watched an interview in which a mother says her son doesn't make any effort, nor study and even so, obtains the best scores in his class because he is very intelligent. (Effort Dimension)
11. A politician says African children who live in impoverished environments will never become as intelligent as children who live in developed countries. (Culture Dimension)
12. A mother says she signs her son up for computer, painting, and horse riding classes so they will make him more intelligent (Context Dimension)
13. My grandma says women can become as intelligent as men if they strive for it. (Gender Dimension)
14. A father says to her daughter that whatever she does won't change her intelligence (Control Dimension)
15. According to my teacher, Einstein was a very intelligent person, and all his achievements were not because of his effort, but because he was born with the gift of intelligence. (Heredity Dimension)
16. A child says he feels intelligent after having learnt to do a new school task. (Training Dimension)
17. In the radio, it has been said that Finnish children are more intelligent because they live in a more developed society. (Culture Dimension)
18. My teachers have always told us intelligence and good behavior belong together. (Associated Qualities Dimension)
19. My friend José says that in our species men are more intelligent than women. (Gender Dimension)
20. In Facebook, a secondary education student writes: 'If you believe you are intelligent, you'll finally become an intelligent person, even though you were not'. (Expectations Dimension)
21. An adolescent says he is very intelligent because he knows how to draw very well. (Diversity of Intelligence Dimension)
22. A girl says that thanks to her parents help and support, she was able to become an intelligent person. (People Dimension)
23. I have read in a blog that, as scientists say maturation ends in adolescence; intelligence cannot be improved beyond that moment. (Critical Period Dimension)
24. One of my teachers said: 'If your teachers support you to become intelligent, you'll end up being intelligent'. (People Dimension)
