26

27 **Abstract**

28 Different white winemaking by-products (pomace, skins, seeds and stems) were  
29 compared as natural sources of phenolic compounds having biological and sensory  
30 properties of oenological interest. Antioxidant and copigmentation effects of these by-  
31 products were studied in wine-like model solution. RRLC-DAD was used to establish  
32 differences on the phenolic composition and the ABTS method to compare the  
33 antioxidant activity. Spectrophotometric and colorimetric analyses were performed to  
34 asses the magnitude of copigmentation and the changes induced in the color  
35 expression of red wine anthocyanins. Antioxidant and copigmentation properties  
36 significantly varied depending on the type of by-product, which was related to their  
37 qualitative and quantitative phenolic composition. Seeds and pomace showed the  
38 highest antioxidant potential while skins and pomace led to the strongest and visually  
39 perceptible color effects on red wine anthocyanins by multiple copigmentation (darker,  
40 more saturated and vivid bluish colors). Results open the possibility of technological  
41 applications for the wine industry based on re-using winemaking by-products to improve  
42 the biological value and color characteristics of red wines.

51

## 52 INTRODUCTION

53 Nowadays, an efficient management of by-products derived from the elaboration  
54 and processing of agricultural products is a necessary requirement for a sustainable  
55 food industry<sup>1</sup>.

56 Focusing on the wine industry, research has consistently demonstrated the  
57 important environmental impact of the liquid and solids residues obtained from the  
58 grape vinification such as wine lees, pomaces, stems, or wastewater sludge; and the  
59 technical and economic difficulties to their elimination or transformation<sup>2-3</sup>. Problems  
60 associated with the management of winemaking by-products are related to their high  
61 organic loading which makes difficult their biological degradation. On the other hand, as  
62 winemaking is a seasonal activity, an intensive accumulation of residues is generated  
63 during a short period every year (grape harvesting), especially in high production  
64 regions. Under these circumstances, the European Union is becoming exigent about  
65 the preservation of water, soil, and biodiversity, and seriously promotes to wine  
66 producers regions looking for new initiatives that permit a more sustainable  
67 management and exploitation of their winemaking by-products (Council Regulation (EC)  
68 n° 491/2009).

69 Traditionally, winemaking by-products have been sent to distilleries for obtaining  
70 ethanol, or to be used as fertilizers or biomass. However, these activities are usually  
71 carried out by external companies representing economic costs for the wine industry<sup>2</sup>.  
72 In consequence, there is an increasing interest to find alternative solutions for the  
73 exploitation and valorization of those by-products, which would involve economic, social  
74 and environmental advantages<sup>4-7</sup>

75

76

77 Over the last decade, the chemical composition of winemaking by-products have  
78 been extensively investigated and was confirmed that they represent low-cost sources  
79 of many bioactive compounds, being even richer than other types of agri-food wastes<sup>8</sup>.  
80 Especially important at this respect are phenolic compound which have potential  
81 industrial applications (pharmaceutical, cosmetic, nutritional or agricultural) due to their  
82 strong antioxidant, anti-inflammatory, antimicrobial, or biostimulant effects<sup>9-12</sup>. These  
83 compounds have also interesting applications in the field of oenology not only for being  
84 responsible of the antioxidant properties of wines but also for playing a crucial role in  
85 organoleptic characteristics such as color, aroma or taste<sup>13</sup>. Particularly in red wines, it  
86 is well known that colorless phenolics are involved in the chemical stabilization of  
87 anthocyanin pigments by means of non-covalent interactions through intermolecular  
88 copigmentation reactions<sup>14</sup>. Studies carried out in model solution and focused on the  
89 application of objective color measurements have demonstrated that copigmentation  
90 cause the stabilization of the colored forms of the anthocyanins and consequently  
91 enhance their color<sup>15,16</sup>. Thus, copigmentation is considered a relevant interaction  
92 because obtaining wines with stable and attractive colors is a major focus for quality  
93 control purposes. Among grape components, colorless phenols including flavonoids and  
94 some phenolic acids appeared as good anthocyanin copigments, which are abundant  
95 compounds in winemaking by-products. Moreover, these compounds can act as  
96 effective oxidation substrates, which partially avoid undesirable color changes due to  
97 browning/oxidation. In fact, it has been recently reported that the addition of dehydrated  
98 waste grape skins during winemaking increased the concentration of some flavonoids in  
99 wines preventing the color loss during storage<sup>17,18</sup>.

100 Despite their potential use in oenology, winemaking by-products have received  
101 little attention in comparison to other wine additives (wood chips, enzymes, enological

102 tannins, etc.) probably due to the difficulties related to the technical and legal concerns  
103 of its application. However, their application as natural wine additives could represents  
104 a sustainable alternative to maximize the exploitation of this valuable agricultural waste  
105 as well as to improve the quality of wines making them more competitive. In this sense,  
106 further investigations are needed to advance the knowledge of the contribution of these  
107 agricultural by-products to wine colour and colour stability.

108 Therefore, the main objective of this study was to compare the potential of  
109 different white winemaking by-products (pomace, seeds, skins and stems) as natural  
110 sources of antioxidants and copigments, in model solution. The information reported in  
111 this work could be useful for high production winemaking areas.

112

## 113 **MATERIALS AND METHODS**

### 114 **Standards and Reagents**

115 Gallic acid, protocatechuic, caffeic and caftaric acids, (+)-catechin (C), (–)-epicatechin  
116 (EC), quercetin, kaempferol, myricetin, sodium carbonate, potassium persulphate and  
117 tartaric acid were purchased from Sigma-Aldrich (Madrid, Spain) and malvidin-3-  
118 glucoside from Extrasynthese (Genay, France). Procyanidin dimer B1 standard was  
119 isolated in the laboratory by semipreparative HPLC<sup>19</sup>.

120 2,2-Azinobis(3-ethylbenzothiazoline-6-sulfonic acid) diammonium salt (ABTS) and  
121 Trolox (6-hydroxy-2,5,7,8-tetramethylchroman-2-carboxylic acid) were purchased from  
122 Fluka (Madrid, Spain), and HPLC grade acetonitrile was from Carlo Erba (Rodano,  
123 Italy). Folin reagent, ethanol and formic acid were obtained from Panreac (Barcelona,  
124 Spain).

### 125 **Winemaking by-products and sample preparation**

126 White winemaking by-products from Zalema grapes (*Vitis vinifera* sp.) used in  
127 this study were: pomace (PM), skins (SK), seeds (SD) and stems (ST). They were  
128 obtained from a winery located in “Condado de Huelva” Designation of Origin (south-  
129 western Spain). Zalema cultivar was selected because is a high production variety rich  
130 in phenolic compounds that represent the main and more extensively white grape  
131 cultivated in the zone.

132 Pomace is the main organic winemaking by-product generated from grape  
133 vinification which is constituted by a mixture of skins and pulp rests, seeds and stems.  
134 3 kg of pomace was collected the day of harvest after Zalema grapes were pressing for  
135 winemaking.

136 In order to be also individually used in the experiments, particles of stems, seeds,  
137 and skins were manually separated from the pomace. All winemaking by-products were  
138 stored at -20 °C and further freeze-dried (lyophilizer Cryodos-80, Telstar® Varian DS  
139 102) until being extracted. The moisture contents of by-products were 50% PM, 40%  
140 ST, 30% SD and 70% SK.

141 The extraction of the non-anthocyanin phenolic compounds from each  
142 winemaking by-product was carried out in wine-like medium containing 5 g/L tartaric  
143 acid in 12% ethanol, buffered with 1 M NaOH to pH 3.6 and ionic strength adjusted to  
144 0.2 M. by addition of NaCl. For this purpose, 2 g of the homogeneous lyophilised  
145 powder of samples (PM, SD; SK and ST) was individually macerated in 15 mL of wine-  
146 like medium for 12 h at room temperature (18-20 °C), with occasional agitation and  
147 sonication. The supernatants were centrifuged (4190 g, 10 min) to separate out the  
148 liquid fraction containing the phenolic compounds extracted, which was filtered through  
149 0.45 µm Millipore-AP20 filters (Bedford, MA).

150 The crude phenolic solution obtained from each winemaking by-product was  
151 analysed for its phenolic composition (spectrophotometric and chromatographic analysis)  
152 and antioxidant activity. Also, they were used as crude mixture of colorless phenolics  
153 (copigments) of wine anthocyanins in copigmentation experiments.

#### 154 **Total phenolic content**

155 The spectrophotometric determination of the total phenolic content was  
156 performed with a Hewlett–Packard UV-vis HP8453 spectrophotometer (Palo Alto, CA,  
157 USA), using 10 mm path length glass cells and distilled water as reference.

158 Total phenolic content of the samples was determined using the Folin-Ciocalteu  
159 method<sup>20</sup>. Briefly, 0.25 mL of sample, 1.25 mL of Folin-Ciocalteu reagent, and 3.75 mL  
160 of a solution of sodium carbonate at 20% were mixed, and distilled water was added to  
161 make up a total volume of 25 mL. The solution was homogenized and left to stand for  
162 120 min for the reaction to take place and stabilize. Absorbance was measured at 765  
163 nm. Gallic acid was employed as a calibration standard and results were expressed as  
164 gallic acid equivalents (mg GAE/L).

#### 165 **Phenolic composition analysis**

166 Rapid resolution liquid chromatography (RRLC) was performed on an Agilent 1260  
167 system equipped with a diode-array detector. Samples were filtered through to 0.45- $\mu$ m  
168 pore size membrane filter and 30  $\mu$ L of samples were injected in a C18 Poroshell 120  
169 column (2.7  $\mu$ m particle size, 5 cm x 4.6 mm; Agilent, Palo Alto, CA) maintained at  
170 25 °C. Water-formic acid (99:1, v/v) as solvent A and acetonitrile as solvent B were  
171 used, setting the flow-rate at 1.5 mL/min. The linear gradient elution was 0 min, 100%  
172 A; 5 min, 95% A and 5% B; 20 min, 50% A and 50% B; 22 min, 100% A; 25 min, 100%  
173 A. The wavelengths of detection were 280 nm (flavanols and benzoic acids), 320 nm  
174 (hydroxycinnamic acids and their tartaric esters) and 370 nm (flavonols).

175 Phenolic compounds were identified by their retention time, UV-vis spectra and mass  
176 spectra data in an API 3200 Qtrap (Applied Biosystems, Darmstadt, Germany)  
177 equipped with an ESI source, and a triple quadrupole-ion trap mass analyser, as  
178 described by Jara-Palacios et al.<sup>21</sup>. The identification of phenolic compounds was  
179 achieved by the comparison of the retention times and mass spectra with those of the  
180 available pure standards and our data library.

181 The external calibration method was used for quantification, by comparing the areas  
182 with standards of gallic, protocatechuic, caffeic and *p*-coumaric acids, catechin,  
183 epicatechin, procyanidin B1, quercetin and kaempferol. Caftaric and coumaric acids were  
184 quantified using the calibration curves of caffeic and *p*-coumaric acids, respectively.  
185 Procyanidin dimers B2, B3 and B4, procyanidin B2-3-*O*-gallate, trimers and tetramer  
186 were quantified with the calibration curve of procyanidin B1. Quercetin and isorhamnetin  
187 derivatives were quantified as quercetin, and kaempferol derivatives as kaempferol.

188 Total phenolic acids, total flavanols, total flavanol oligomers and total flavonols, were  
189 also calculated by the sum of individual phenolic acids, flavanols, flavanol oligomers,  
190 and flavonols identified, respectively. The samples were analyzed in triplicate and the  
191 results expressed as mg/L.

### 192 **Antioxidant activity**

193 The antioxidant activity was measured *in vitro* based on the ability to scavenge  
194 the ABTS<sup>•+</sup> radical<sup>22</sup>. The ABTS<sup>•+</sup> radical was produced by the oxidation of 7 mM ABTS  
195 with potassium persulphate (2.45 mM) in water. The mixture was kept in the dark at  
196 room temperature for 16 h before using it, and then the ABTS<sup>•+</sup> solution was diluted with  
197 phosphate buffered saline (PBS) at pH 7.4 to give an absorbance of  $0.70 \pm 0.02$  at 734  
198 nm. Then, 50  $\mu$ L of each sample was mixed with 2 mL of the ABTS<sup>•+</sup> diluted solution,  
199 vortexed for 10 s, and the absorbance was measured at 734 nm after reacting 4 min at

200 30 °C. Results were obtained by interpolating the absorbance of samples on a  
201 calibration curve obtained with Trolox (30-1,000 µM). Three independent experiments in  
202 triplicate were performed for each sample and the results were expressed as Trolox-  
203 equivalent antioxidant activity (TEAC; µmols of Trolox-equivalent (TE) with the same  
204 antioxidant activity of 1 L of sample).

### 205 **Copigmentation experiments**

206 Copigmentation experiments were carried out in wine-like medium using a crude  
207 anthocyanin solution prepared from Syrah red grapes and different crude phenolic  
208 solutions (colorless copigments) obtained from white winemaking by-products.

209 The crude anthocyanin solution was obtained by macerating 1 g of  
210 homogeneous lyophilised powder of Syrah skins in 20 mL of wine-like medium (the  
211 same previously described), for 12 h with occasional agitation and sonication. Then, it  
212 was centrifuged (4190 *g*, 10 min) and the supernatant filtered through 0.45 µm Millipore-  
213 AP20 filters (Bedford, MA). The phenolic composition (anthocyanin pigments and other  
214 colorless monomeric phenols) of the crude anthocyanin solution was analysed by HPLC  
215 following the method described in Gordillo et al.<sup>23</sup>.

216 Copigmented solutions were prepared by adding separately each crude phenolic  
217 solution from winemaking by-products (PM, ST, SD, SK) to the crude anthocyanin  
218 solution at seven levels (50, 100, 200, 300, 400, 500 and 600 mg/L). The final  
219 anthocyanin concentration was the same in all cases (200 mg/L). All of the solutions (2  
220 mL) were prepared in triplicate and equilibrated to reach the equilibrium for 2 h and  
221 stored closed in darkness at 25 °C, after which their absorption spectra were recorded.

### 222 **Colorimetric measurement**

223 The absorption spectra (380- 770 nm) of all solutions were recorded at constant  
224 intervals ( $\Delta\lambda=2$  nm) with a Hewlett- Packard UV-vis HP8453 spectrophotometer (Palo  
225 Alto, CA), using 2 mm path length glass cells and distilled water as a reference.

226 The CIELAB parameters ( $L^*$ ,  $a^*$ ,  $b^*$ ,  $C^*_{ab}$ , and  $h_{ab}$ ) were calculated from the  
227 absorption spectra by using the original software CromaLab<sup>®</sup> 24, following the  
228 recommendations of the Commission International de L'Eclairage<sup>25</sup>: the 10° Standard  
229 Observer and Standard Illuminant D65.

230 Color difference ( $\Delta E^*_{ab}$ ) was determined by applying the CIE76 color difference  
231 formula. It was calculated as the Euclidean distance between two points in the three-  
232 dimensional CIELAB space defined by  $L^*$ ,  $a^*$  and  $b^*$ :  $\Delta E^*_{ab} = [(\Delta L^*)^2 + (\Delta a^*)^2 + (\Delta b^*)^2]^{1/2}$ .  
233 It is assumed that color differences ( $\Delta E^*_{ab}$ ) higher than 3-5 units can be perceived by an  
234 average observer<sup>26</sup>.

### 235 **Copigmentation measurements**

236 The spectrophotometric determination of the magnitude of the copigmentation  
237 was made by comparing the absorbance at 520 nm of the crude anthocyanin solution  
238 ( $A_0$ ) and the absorbance at 520 nm of the same solution containing different crude  
239 phenolic mixtures from white winemaking by-products ( $A_c$ ), at each concentration level  
240 and expressed as the percentage  $[(A_c - A_0)/A_0] \times 100^{27}$ .

241 The color variation due to copigmentation was also evaluated by Tristimulus  
242 Colorimetry according to the methodology described in Gordillo et al.<sup>16</sup>, which offers an  
243 objective measurement of color because it is based on the consideration of the whole  
244 visible spectrum, and allows the real assessment of color to be obtained. Following this  
245 methodology, diverse color-difference formulas were applied in the CIELAB color space  
246 by using the scalar ( $L^*$ ,  $a^*$ ,  $b^*$ ) and cylindrical ( $L^*$ ,  $C^*_{ab}$ ,  $h_{ab}$ ) CIELAB color coordinates of  
247 samples. This provides a better evaluation of the quantitative and qualitative color

248 implications of the copigmentation, and their incidence on visual perception. The new  
249 colorimetric variables were determined as follows:

250 - The Total Color of each sample was assessed as the CIELAB color difference ( $\Delta E^*_{ab}$ )  
251 applied between its color ( $L^*$ ,  $a^*$ , and  $b^*$ ) with respect to distilled water ( $L^*=100$ ,  $a^*=0$ ,  
252  $b^*=0$ ), as shown in Eq. (1). It represents a quantitative color attribute.

253

254 Eq. (1) Total Color:  $\Delta E^*_{ab} = [ (L^* - 100)^2 + (a^* - 0)^2 + (b^* - 0)^2 ]^{1/2}$

255

256 - The Total Color Difference induced by copigmentation was assessed as the CIELAB  
257 color difference ( $\Delta E^*_{ab}$ ) applied between the color of the crude anthocyanin solution  
258 ( $L^*_0$ ,  $a^*_0$ , and  $b^*_0$ ) and the color of the same solution copigmented with each crude  
259 phenolic mixture from white winemaking by-products ( $L^*_c$ ,  $a^*_c$ , and  $b^*_c$ ), as shown in Eq.  
260 (2):

261

262 Eq. (2) Total Color Difference:  $\Delta E^*_{ab(c-0)} = [ (L^*_c - L^*_0)^2 + (a^*_c - a^*_0)^2 + (b^*_c - b^*_0)^2 ]^{1/2}$

263

264 - The relative contribution (%) of lightness, chroma and hue to each Total Color  
265 Difference induced by copigmentation was calculated by means of the color formulas  
266 shown in Eq. (3, 4, and 5). They represent the weight of the three color attributes that  
267 makes up the total color difference.

268 Eq. (3) Relative contribution (%) of lightness:  $\% \Delta L = [ (\Delta L_{c-0})^2 / (\Delta E^*_{ab(c-0)})^2 ] \times 100$

269 Eq. (4) Relative contribution (%) of chroma:  $\% \Delta C = [ (\Delta C_{c-0})^2 / (\Delta E^*_{ab(c-0)})^2 ] \times 100$

270 Eq. (5) Relative contribution (%) of hue:  $\% \Delta H = [ (\Delta H_{c-0})^2 / (\Delta E^*_{ab(c-0)})^2 ] \times 100$

271 being  $\Delta H_{c-0}$  deduced as follows:  $\Delta H_{c-0} = [ (\Delta E^*_{ab(c-0)})^2 - ((\Delta L_{c-0})^2 + (\Delta C_{c-0})^2) ]^{1/2}$

272

## 273 **Statistical analysis**

274 All statistical analyses were performed using Statistica v.8.0 software<sup>28</sup>.  
275 Univariate analysis of variance (Tukey test) was applied to establish differences for the  
276 phenolic composition, antioxidant activity and copigmentation effects among the crude  
277 phenolic solutions from winemaking by-products (GP, SD, SK and ST). Moreover,  
278 correlations between the phenolic composition (main phenolic groups or individual  
279 phenolic compounds) and the antioxidant activity was studied by linear and multiple  
280 regressions. In all cases (differences or correlations), statistically significant level was  
281 considered at  $p < 0.05$ .

## 282 **RESULTS AND DISCUSSION**

### 283 ***Phenolic composition***

284 A total of 24 phenolic compounds were identified and quantified in the crude  
285 phenolic solutions from winemaking by-products by using the methodology and the  
286 chromatographic conditions previously described. The phenolic profile of samples  
287 showed the presence of several types of monomeric and oligomeric colorless phenols  
288 belonging to diverse phenolic families. The benzoic acids, hydroxycinnamic acids,  
289 flavanols, and flavonols identified were the expected, well-known, compounds usually  
290 present in grapes. It included 6 phenolic acids (gallic, protocatechuic, caftaric, caffeic,  
291 *cis*-coutaric and *trans*-coutaric acids); 2 monomeric flavanols (catechin and  
292 epicatechin), 8 oligomeric flavanols (procyanidins B1, B2, B3, B4 and B2-3-*O*-gallate,  
293 two trimers and one tetramer); and 8 flavonols (quercetin and kaempferol aglycones,  
294 and 3-glycosides conjugated forms of quercetin, kaempferol and isorhamnetin).

295 Table 1 summarizes the concentration for the mentioned phenolic compounds  
296 (mg/L) and the total phenolic content (mg GAE/L) of samples, showing the statistical  
297 differences found among them. In general terms, all samples presented important

298 contents of total phenolics indicating that considerable amounts of bioactive compounds  
299 can be recovered from Zalema winemaking by-products. As white wines are commonly  
300 elaborated by applying a shorter maceration time than red wines, the pomace obtained  
301 from white vinification is not as exhausted as that from red vinification, which increase  
302 its industrial value as richer agricultural by-product<sup>18</sup>. Nevertheless, significant  
303 differences ( $p < 0.05$ ) were found for the total phenolic content among samples  
304 depending on the type of winemaking by-product. The crude phenolic solution from SD  
305 showed the highest total phenolic content (around two-fold the concentration of the  
306 other samples), which is consistent with previous reports<sup>29</sup>. The higher accumulation of  
307 phenolic compounds in seeds<sup>30</sup> but the lower extractability due to the solid cellular  
308 structure<sup>31</sup> could explain the greater phenolic potential of SD as winemaking by-product.  
309 On the contrary, significant ( $p < 0.05$ ) lower contents of total phenolics was found in the  
310 crude phenolic solutions from SK and ST, indicating that they are comparatively poorer  
311 sources of phenolics.

312 The chromatographic analysis showed that crude phenolic solutions from PM,  
313 SK, SD, and ST had different qualitative and quantitative phenolic profile (Figure 1),  
314 being the differences significant ( $p < 0.05$ ) for most of the individual compounds identified  
315 (Table 1). These differences were also observed when compounds were grouped by  
316 phenolic families (phenolic acids, flavanols and flavonols). Significant higher contents of  
317 flavanols were found in the crude phenolic solutions from SD, which is in accordance  
318 with other reports<sup>8, 32</sup>. The global level of flavanols was 35% higher than those found in  
319 the samples from PM and 64% higher than those from SK and ST. On the other hand,  
320 PM was the major source of phenolic acids, contributing to the crude phenolic solution  
321 with 34% higher than ST and SD, and with 38% higher than SK. As regards the flavonol

322 contribution, SK represented the significant richest source of these compounds in  
323 comparison with all other winemaking by-products studied, as expected.

324 As far as individual compounds are concerned, great variability has been  
325 described in the literature about the distribution of phenolic acids in different types of  
326 winemaking by-products, which is attributable to the influence of several factors as  
327 grape variety, cultivation and climatic conditions, or the oenological processes applied  
328 during the winemaking<sup>33-35</sup>. However, the qualitative profile of phenolic acids did not  
329 differ much among samples. In particular, gallic acid was the main phenolic acid found  
330 in the samples being transferred in significant ( $p < 0.05$ ) higher quantity by PM. Caftaric  
331 acid was the second most abundant phenolic acid, being ST and PM the better sources.

332 In contrast, the group of flavonoids (flavanols and flavonols) varied considerably  
333 among samples. In the case of flavanols, significant higher levels of monomeric  
334 compounds were obtained from SD, mainly due to a more important contribution in  
335 catechin and epicatechin. Nevertheless, Zalema winemaking by-products contributed  
336 with greater quantities of oligomers than monomers to the total flavanol content (PM:  
337 84%, SK: 80%, ST: 75% and SD: 70%). Among them, procyanidin B1, B4 and B2-3-*O*-  
338 gallate were the most representative oligomers in all samples. Specifically, SD and PM  
339 were the significant richest sources in oligomeric flavanols (98.9 and 77.3 mg/L in  
340 samples, respectively), contributing to the crude phenolic solution about 2.5-fold higher  
341 than SK and ST. Regarding flavonols, quercetin-3-glucoside was the predominant  
342 compound in all samples. The crude phenolic solution from SK was noteworthy for  
343 having significant higher levels of all flavonols compared to those from PM, ST and SD  
344 (6.6% of the total phenolic contribution versus 2.3%, 1.7%, and 0.3%, respectively).

345 The individual phenolic compound present in the crude phenolic solution have  
346 critical importance since each single compound can have different antiradical and

347 copigmentation power<sup>36,37</sup>. Thus, based on the results obtained, differences on the  
348 antioxidant and copigmentation properties of samples were expected as well, since  
349 different heterogeneous phenolic mixtures coexisting in competing equilibria might  
350 result in additive or suppressive effects<sup>8,15</sup>.

351

### 352 ***Antioxidant activity***

353 Results showed that the antioxidant activity was in accordance with the total  
354 phenolic content of each sample (Table 1). Thus, the crude phenolic solution from SD,  
355 with the highest phenolic content showed the greatest antioxidant activity (888.7  $\mu\text{mol}$   
356 TE/L) followed in decreasing order by those from GP, ST, and SK (463.3, 305.6, and  
357 297.5  $\mu\text{mol}$  TE/L, respectively).

358 Univariate linear regression was applied to these data in order to explore  
359 relationships between the total phenolic content and the antioxidant activity, and very  
360 strong and significant correlations ( $R^2 = 0.98$ ,  $p < 0.05$ ) were found, which indicate that  
361 Zalema winemaking by-products represent good sources of natural antioxidants with  
362 high added value.

363 Also a multiple regression analysis was performed to check the more influencing  
364 phenolic groups (independent variables: total phenolic acids, total flavanols and total  
365 flavonols) on the antioxidant activity (dependent variable). High multiple correlation  
366 coefficient ( $R^2 = 0.99$ ) and significant correlation ( $p < 0.05$ ) were obtained for the total  
367 flavanols ( $\beta = 0.98$ ) followed by the total phenolic acids ( $\beta = -0.18$ ).

368 On the other hand, two multiple regression analyses were carried out in order to  
369 determine the relative importance of individual phenolic compounds on the antioxidant  
370 activity. First, a regression analysis between antioxidant activity (dependent variable)  
371 and individual flavanols (independent variables) was performed to assess the influence

372 of these phenolic compounds. Results indicated good correlation ( $R^2=0.98$ ) having  
373 catechin ( $\beta= 0.83$ ), epicatechin ( $\beta= 1.01$ ), trimer C1 ( $\beta= 1.28$ ) and procyanidins B2 ( $\beta=$   
374  $0.54$ ) and B4 ( $\beta= 0.68$ ) significant influence ( $p<0.05$ ). Multiple regression analysis  
375 considering phenolic acids showed also high multiple correlation coefficient ( $R^2=0.99$ )  
376 having caffeic acid ( $\beta= -2.20$ ), caftaric acid ( $\beta= 1.33$ ), *trans*-coutaric acid ( $\beta= -1.20$ ) and  
377 gallic acid ( $\beta= 1.22$ ) more influence than *cis*-coutaric and protocatechuic acids.

378

### 379 **Copigmentation effect**

380 The crude anthocyanin solution obtained from Syrah skins was analyzed for its  
381 phenolic composition. Eleven anthocyanins including non-acylated, acetylated and p-  
382 coumaroylated forms of the five expected anthocyanidins (delphinidin, cyanidin,  
383 petunidin, peonidin and malvidin) were identified by HPLC, which accounted for 95.8%  
384 of the total phenolic content. Also, the presence of other minor non-anthocyanin  
385 phenolic compounds was confirmed. They were mainly flavonols and phenolic acids  
386 which accounted for less than 5% of the total phenolic compounds identified. The  
387 relative proportion of each identified compound is presented in Table 2.

388 Figure 2 shows the magnitude of copigmentation (2a) and the Total Color (2b) of  
389 the crude anthocyanin solution containing increasing concentrations of crude phenolic  
390 solutions from Zalema winemaking by-products (PM, SK, SD and SK). Immediate  
391 intermolecular copigmentation was observed in the mixtures, which are evidenced by  
392 the hyperchromic shift of the  $\lambda_{max}$  of the crude anthocyanin solution (520 nm) and also  
393 by an increase of its initial Total Color (26.6 CIELAB u.). As observed, the magnitude of  
394 copigmentation differed depending on the type of winemaking by-product and the  
395 phenolic concentration applied. Stronger copigmentation effects were produced by the  
396 crude phenolic solutions from SK and PM, which induced the highest hyperchromic

397 shifts (from 2% to 28% and from 11% to 24%, respectively) and increases of the Total  
398 Color (from 26.6 to 34.4 and 32.5 CIELAB u., respectively). The effect was significantly  
399 ( $p < 0.05$ ) more pronounced with increasing copigment concentration. In contrast, SD  
400 and ST appeared as the less effective sources of copigments since the addition of the  
401 crude phenolics solutions at increasing levels not resulted always in progressive  
402 increases of the magnitude of copigmentation neither in the Total Color.

403 Our results indicate that the quantitative and qualitative profile of phenolic  
404 mixtures used as colorless copigments determined distinctive effects on the extend of  
405 multiple copigmentations, as previously reported by Gonzalez-Manzano et al.<sup>15</sup>. Higher  
406 relative proportions of more effective copigments as flavonols (mainly quercetin  
407 derivatives), oligomeric flavanols (mainly B-type procyanidins) or some phenolic acids in  
408 SK and PM samples could explain their greater copigmentation effect observed<sup>36</sup>.

409 Also, it was confirmed that the color of the crude anthocyanin solution was  
410 improved by the crude phenolic solution from winemaking by-products, which was  
411 manifested through positive changes in the CIELAB parameters ( $L^*$ ,  $C^*_{ab}$  and  $h_{ab}$ ),  
412 showed in Figures 3a, 3b, and 3c). The progressive enrichment on colorless  
413 copigments resulted in decreasing lightness and hue values ( $L^*$  and  $h_{ab}$ ) and increasing  
414 chroma ( $C^*_{ab}$ ), which means a progressive darker and more saturated bluish color.  
415 However, important differences existed for the quantitative and qualitative color effects  
416 induced depending on the type of winemaking by-product. In this sense, crude phenolic  
417 solutions from PM and SK decreases the initial values of lightness approximately by 6%  
418 (from 86.5 to 81.3 and 81.8 CIELAB u. , respectively) and increases the chroma value  
419 by 24% and 19% (from 22.9 to 28.5 and 27.4 CIELAB u.). Concerning the qualitative  
420 attribute of color ( $h_{ab}$ ), the effect was more important with crude phenolic solution from

421 PM and ST, which decreases the initial hue value approximately in 3 grades ( from -  
422 8.26° to -11.33° and -10.29°)

423 The Total Color Differences,  $\Delta E^*_{ab (C-0)}$ , between the crude anthocyanin solution  
424 and those containing crude phenolic solution from winemaking by-products at  
425 increasing concentration were calculated (Figure 4), which provide a relevant color  
426 information related to visual perception. Moreover, the relative contribution of lightness  
427 (% $\Delta L$ ), chroma (% $\Delta C$ ), and hue (% $\Delta H$ ) to each color difference calculated permit us an  
428 objective comparison of the colorimetric effect among the samples. Results showed that  
429 the color changes were visually perceptible ( $\Delta E^*_{ab} > 3$ , according to Martínez et al.<sup>26</sup>) for  
430 the crude phenolic solution from PM at all the assayed concentrations, as well as for  
431 most of those from SK. On contrast, samples from SD and ST resulted in color  
432 differences lower than 3 CIELAB u. (not clearly perceptible). This fact confirm again  
433 their poorer efficiency as copigments sources, which is consistent with the results  
434 obtained for the magnitude of copigmentation and Total Color.

435 Regarding winemaking by-products causing perceptible color changes (SK and  
436 PM), it can be observed that both samples induced similar effects independently of the  
437 concentration tested. In general, the weight of the lightness and chroma modifications  
438 were more marked than in hue (% $\Delta L$ =54% and 52%; % $\Delta C$ = 45% and 45.5; % $\Delta H$ = 0.1%  
439 and 2%, as mean values respectively in SK and PM). This meant that for the same  
440 concentration of the SK and PM crude phenolic solutions, comparable darkening and  
441 greater quantity of color was induced without substantially modify the original hue.

442 In summary, white winemaking by-products from Zalema grape are rich sources  
443 of phenolic compounds consisting of mainly flavanoids and phenolic acids. The  
444 antioxidant activity of these compounds is related to the total phenolic content and  
445 particularly to the flavanols and phenolic acids contents. The copigmentation effects in

446 model solution indicate that white winemaking by-products could improve the  
447 anthocyanin color quality depending on the type of by-product used as copigment  
448 source (PM, SK, SD, and ST) and the phenolic concentration applied, causing  
449 perceptible color changes. Therefore, the exploitation for their potential reuse in the  
450 wine industry could be of great interest, either considering the Zalema pomace or its  
451 individual components (seeds, stems and skins).

452

453

454 **ACKNOWLEDGEMENTS**

455 Authors are indebted to Vinícola del Condado winery ("Condado de Huelva" D.O.) for  
456 supplying samples and to Dr. Modesto J. Carballo (Biology Service, CITIUS,  
457 Universidad de Sevilla) for the technical assistance.
