Abstract

In this paper, some new properties of the upper-corrected orthant of a random vector are proved. The univariate right-spread or excess wealth function, introduced by Fernández-Ponce *et al.* (1996), is extended to multivariate random vectors, and some properties of this multivariate function are studied. Later, this function was used to define the excess wealth ordering by Shaked and Shanthikumar (1998) and Fernández-Ponce *et al.* (1998). The multivariate excess wealth function enable us to define a new stochastic comparison which is weaker than the multivariate dispersion orderings. Also, some properties relating the multivariate excess wealth order with stochastic dependence are described.

Keywords: Excess Wealth Function; Expansion Function; Multivariate Dispersion Ordering; Quantile; Upper-corrected Orthant.

1. Introduction

Comparisons among univariate random variables in some stochastic sense have been extensively studied by many authors during the last thirty years. There exist many applications of these stochastic orderings, from economic theory to reliability and queueing theory (see Barlow and Proshan, 1975; Stoyan, 1983; Shaked and Shanthikumar, 1994). In particular, variability orders for univariate distributions have found a profound interest among researchers. Among these types of orders, the dispersion ordering has

been well studied. Two interesting papers on the dispersion ordering (d.o.) are the ones by Shaked (1982) and Deshpandé and Kochar (1983). This order was characterized through the number of crossings and the corresponding changes of sign for the distribution functions (see Hickey, 1986; Muñoz-Pérez, 1990; Saunders, 1984, and Bartoszewicz, 1995). Bartoszewicz (1995) characterized the d.o. using the TTT transforms and he found a relationship between the order based on the mean residual lives and the d.o. (see Bartoszewicz, 1997). Kochar (1996) studied the d.o. among order statistics from DFR distributions.

The d.o. has been also considered to characterize lifetime

¹Corresponding author

distributions satisfying particular aging properties; different characterizations for IFR and DFR random variables by means of the d.o can be seen, for example, in Pellerey and Shaked (1997). Other types of aging properties for lifetime distributions, weaker than IFR, have been proposed in Kochar and Wiens (1987). Thus, a characterization in dispersion sense for these distributions needed of a new comparison again based on dispersion but weaker than the classic d.o. For this reason, Fernández-Ponce *et al.* (1996) gave the concept of right-spread function, which characterized the aging notions defined in in Kochar and Wiens (1987). In a parallel direction and in an independent way, Shaked and Shanthikumar (1998) defined the same function which was named by them as the excess wealth function. The analysis of a new weak dispersion ordering, which was called excess wealth order, was developed in Shaked and Shanthikumar (1998) and Fernández-Ponce *et al.* (1998). Later several authors have characterized lifetime distributions using this partial order (see Kochar and Carrière, 1997 and Kochar, *et al.*, 2001 among others).

In this paper, a multivariate generalization of the excess wealth function is defined and studied, and a multivariate stochastic comparison is introduced. The relationships between this comparison and other orders based on dispersion, and in dependence properties, are investigated. Also, a new characterization of the CIS (Conditionally Increasing in Sequence) property, whose definition is recalled next, is provided.

The paper is organized in the following way. In Section 2, we further study some properties of the multivariate quantiles which were introduced in Fernández-Ponce and Suárez-Lloréns (2003). In Section 3, we extend the concept of excess wealth function to the multivariate case. In Section 4, the excess wealth order for multivariate distributions is defined and studied. For example, it is shown that the multivariate excess-wealth order is weaker than the multivariate dispersion ordering.

2. Notation and preliminaries

Some notation which will be used throughout the paper is given here. The usual stochastic ordering between univariate random variables is denoted by \leq_{ST} , that is, $X \leq_{ST} Y$ if $P[X \leq x] \geq P[Y \leq x]$ for all x in \mathbb{R} . Fundamentally, random vectors will be dealt with which take on values in \mathbb{R}^n . The space \mathbb{R}^n is endowed with the usual componentwise partial order, which is defined as follows: let $\mathbf{x} = (x_1, \dots, x_n)$ and $\mathbf{y} = (y_1, \dots, y_n)$ be two vectors in \mathbb{R}^n , then $\mathbf{x} \leq \mathbf{y}$ if $x_i \leq y_i$ for $i = 1, \dots, n$. Throughout the paper “increasing” means “non-decreasing” and “decreasing” means “non-increasing”. Particularly, a function $\phi : \mathbb{R}^n \rightarrow \mathbb{R}^n$ is said to be an increasing function when $\phi(\mathbf{x}) \leq \phi(\mathbf{y})$ for $\mathbf{x} \leq \mathbf{y}$. The notation \sim_{st} stands for equality in law. The vector of ones will be denoted by $\mathbf{1}$, i.e.

$\mathbf{1} = (1, \dots, 1)$, and the corresponding of zeros by $\mathbf{0}$. The multiple integral $\int_A F(t_1, \dots, t_n) dt_1 \dots dt_n$ will be denoted as $\int_A F(\mathbf{t}) d\mathbf{t}$. The dimension of a random vector is clear from the context and unless otherwise stated it is assumed that it is n .

Let \mathbf{X} be a random vector in \mathbb{R}^n with distribution function (cdf) $F(\cdot)$. The multivariate \mathbf{u} -quantile for \mathbf{X} , also called *regression representation*, was introduced by O’Brien (1975), Arjas and Lehtonen (1978) and Rüschemdorf (1981). The definition is as follows. Let $\mathbf{u}_n = (u_1, \dots, u_n)$ be a vector in $[0, 1]^n$, the multivariate \mathbf{u} -quantile for \mathbf{X} , denoted by $\hat{\mathbf{x}}(\mathbf{u}_n)$, is defined as

$$\hat{x}_1(u_1) = F_{X_1}^-(u_1), \hat{x}_2(\mathbf{u}_2) = F_{X_2|X_1=\hat{x}_1(u_1)}^-(u_2), \dots, \\ \hat{x}_n(\mathbf{u}_n) = F_{X_n|\bigcap_{j=1}^{n-1} X_j=\hat{x}_j(\mathbf{u}_j)}^-(u_n)$$

where $F^-(u) = \inf\{x : F(x) \geq u\}$ and $\mathbf{u}_i = (u_1, \dots, u_i)$ for all $i = 1, \dots, n$.

Müller and Scarsini (2001) used the multivariate \mathbf{u} -quantile to provide conditions for the stochastic comparison of random vectors with a common copula. Li *et al.* (1996) used this representation as a tool for the construction of multivariate distributions with given non-overlapping multivariate marginals. Shaked and Shanthikumar (1998) also proposed the standard construction as an useful tool for the stochastic comparison of random vectors. Rüschemdorf (2004) used it for the stochastic comparison of risks with respect to supermodular ordering which is of particular interest in many applications.

More recently, Fernández-Ponce and Suárez-Lloréns (2003) also defined several concepts for a multivariate random vector which will be used later on. The first concept is the multivariate \mathbf{x} -rate vector, denoted by $\mathbf{x}^*(\mathbf{x})$, and it is defined as $\mathbf{x}_1^*(x_1) = P(X_1 \leq x_1)$, $\mathbf{x}_2^*(\mathbf{x}_2) = P(X_2 \leq x_2 | X_1 = x_1)$, \dots , $\mathbf{x}_n^*(\mathbf{x}_n) = P(X_n \leq x_n | \bigcap_{j=1}^{n-1} X_j = x_j)$, where $\mathbf{x}_i = (x_1, \dots, x_i)$ for all $i = 1, \dots, n$. The second concept is the right-upper orthant at a point \mathbf{z} , denoted by $C(\mathbf{z})$, and it is defined as $C(\mathbf{z}) = \{\mathbf{x} \in \mathbb{R}^n : \mathbf{z} \leq \mathbf{x}\}$. At the end, the upper-corrected orthant at a point \mathbf{z} for the random variable \mathbf{X} , denoted as $R_{\mathbf{X}}(\mathbf{z})$, is defined as

$$R_{\mathbf{X}}(\mathbf{z}) = \{\mathbf{x} \in \mathbb{R}^n : x_1 \geq F_{X_1}^-(\mathbf{x}_1^*(z_1)), \dots, \\ x_n \geq F_{X_n|\bigcap_{j=1}^{n-1} X_j=\mathbf{x}_j}^-(\mathbf{x}_n^*(\mathbf{z}_n))\}.$$

For notational purposes, to reduce the complexity in the proofs of the results, a slight modification of this notion is considered here, restricting the set only to the points that are in the support of the vector. By taking into account that the support of a random vector \mathbf{X} is defined as $Supp(\mathbf{X}) = \{\mathbf{x} \in \mathbb{R}^n : P[\mathbf{X} \in B_{\mathbf{x}}(\varepsilon)] > 0 \text{ for all } \varepsilon > 0\}$ where $B_{\mathbf{x}}(\varepsilon)$ is the centered ball at \mathbf{x} with radius ε , then the following definition can be given.

Definition 1. Let \mathbf{X} be a random vector. Its upper corrected orthant at $\mathbf{z} \in \text{Supp}(\mathbf{X})$ is defined as

$$R_{\mathbf{X}}(\mathbf{z}) = \{ \mathbf{x} \in \text{Supp}(\mathbf{X}) : x_1 \geq F_{X_1}^-(\hat{x}_1(z_1)), \dots, \\ x_n \geq F_{X_n | \bigcap_{j=1}^{n-1} X_j = x_j}^-(\hat{x}_n(\mathbf{z}_n)) \}.$$

It is easily shown that if \mathbf{X} is a random vector with independent components then $R_{\mathbf{X}}(\mathbf{z}) = C(\mathbf{z}) \cap \text{Supp}(\mathbf{X})$.

Remark 1. Note that if $\mathbf{t}_1 \leq \mathbf{t}_2$ then it could not be held that $R_{\mathbf{X}}(\mathbf{t}_2) \subset R_{\mathbf{X}}(\mathbf{t}_1)$. For example, let \mathbf{X} be a bivariate random vector with joint density function given by

$$f_{\mathbf{X}}(\mathbf{t}) = \begin{cases} 2/3 & \text{if } \mathbf{t} \in T_1; \\ 4/3 & \text{if } \mathbf{t} \in T_2; \\ 0 & \text{otherwise} \end{cases}$$

where T_1 is the triangle with vertices $(0,0)$, $(0,1)$ and $(1,1)$, and T_2 is the triangle with vertices $(0,0)$, $(1,0)$ and $(1,1)$.

Let $\mathbf{t}_1 = (\frac{1}{2}, \frac{1}{2})$. By straightforward computations, it is verified that

$$R_{\mathbf{X}}(\mathbf{t}_1) = \left\{ x \geq \frac{1}{2}, y \geq \frac{x+1}{3} \right\}.$$

Now, consider $\mathbf{t}_2 = (\frac{2}{3}, \frac{1}{2})$. It holds that $\mathbf{t}_1 \leq \mathbf{t}_2$, and $\mathbf{t}_2 \in R_{\mathbf{X}}(\mathbf{t}_2)$. But, $\mathbf{t}_2 \notin R_{\mathbf{X}}(\mathbf{t}_1)$. Thus $R_{\mathbf{X}}(\mathbf{t}_2) \not\subset R_{\mathbf{X}}(\mathbf{t}_1)$.

From now on, assume that the following regularity conditions (RC) are verified by every cdf F in the paper.

1. F is a continuous function.
2. The vector $\hat{\mathbf{x}}(\mathbf{u})$ is differentiable at each component.
3. The conditional distribution of X_i to X_1, \dots, X_{i-1} ($F_{i|1, \dots, i-1}$) is a continuous and strictly increasing function for $i = 1, \dots, n$. For convenience $F_{1|0} = F_1$.
4. $F_{X_i | X_1, \dots, X_{i-1}}^-(0) < \infty$ for all $i = 1, \dots, n$.

It is easy to verify that under the regularity conditions above there is a one to one correspondence between vectors $\mathbf{u}_n \in [0, 1]^n$ and the points $\mathbf{x} \in \text{Supp}(\mathbf{X})$.

The next result is the main reason of interest in the notion of upper corrected orthant. Its proof directly follows from Proposition 2.1 in Fernández-Ponce and Suárez-Lloréns (2003).

Proposition 1. Let \mathbf{X} be a random vector. Then

$$P[\mathbf{X} \in R_{\mathbf{X}}(\hat{\mathbf{x}}(\mathbf{u}_n))] = \prod_{j=1}^n (1 - u_j),$$

for all $\mathbf{u}_n \in [0, 1]^n$.

Furthermore, let $\mathbf{t} = (t_1, t_2)$ be a point in $\text{Supp}(\mathbf{X})$. Then it is easily shown that

$$P(\mathbf{X} \in R_{\mathbf{X}}(\mathbf{t})) = \int_{t_1}^{+\infty} \int_{F_{2|w_1}^-(F_{2|t_1}(t_2))}^{+\infty} f(w_1, w_2) dw_2 dw_1 \\ = \int_{t_1}^{+\infty} f_{X_1}(w_1) \int_{F_{2|w_1}^-(F_{2|t_1}(t_2))}^{+\infty} f_{X_2 | X_1 = w_1}(w_2) dw_2 dw_1.$$

Consequently, it is obtained that

$$P(\mathbf{X} \in R_{\mathbf{X}}(\mathbf{t})) = P(X_1 > t_1)P(X_2 > t_2 | X_1 = t_1). \quad (1)$$

This equality can easily be generalized for the n -dimensional case by using induction arguments.

This result means that the probability associated to the upper corrected orthant at the \mathbf{u}_n -quantile does not depend on the distribution function.

As it can be seen in Proposition 1, the upper corrected orthant plays in the multivariate setting the same role as the u -quantile upper orthant for univariate distributions, being $P[X \in R_X(\hat{x}(u))] = P[X \geq F_X^-(u)] = 1 - u$ in the univariate case. Thus, it is interesting to describe the main properties of upper corrected orthants.

It is well-known that the univariate quantile function is an increasing function, i.e. $u \leq v$ if, and only if $Q_X(u) \leq Q_X(v)$. This property is not verified by random vectors, in general. However if a type of dependence is held then this property can be verified. This type of dependence must be based on the growth of the corresponding conditional distributions. In this way, the following definition of *conditionally increasing in sequence* property can be found in Barlow and Proschan (1975). Also, two interesting results which will be used later are proved.

Definition 2. The random variables X_1, \dots, X_n are *conditionally increasing [decreasing] in sequence (CIS)[CDS]* if X_i is *stochastically increasing [decreasing]* in X_1, \dots, X_{i-1} for $i = 2, \dots, n$.

Theorem 1. \mathbf{X} is a CIS random vector if and only if $R_{\mathbf{X}}(\mathbf{x}) \subset C(\mathbf{x})$ for all $\mathbf{x} \in \mathbb{R}^n$.

Proof. First, we prove the sufficient condition. The proof will be by mathematical induction. The proposition is obviously true for $n = 1$. Assume that the proposition is true for $n = m$. We now need to show that it is true for $n = m + 1$. If $\hat{\mathbf{x}}(\mathbf{u}_m) \leq \mathbf{t}_m$ then, given that \mathbf{X} is CIS,

$$\hat{x}_{m+1 | \hat{\mathbf{x}}_m(\mathbf{u}_m)}(u_{m+1}) \leq \hat{x}_{m+1 | \mathbf{t}_m}(u_{m+1}).$$

However, we know that if $\mathbf{t}_{m+1} \in R_{\mathbf{X}}[\hat{\mathbf{x}}(\mathbf{u}_{m+1})]$ then $t_{m+1} \geq \hat{x}_{m+1 | \mathbf{t}_m}(u_{m+1})$. Therefore, $\mathbf{t}_{m+1} \in C[\hat{\mathbf{x}}(\mathbf{u}_{m+1})]$. Hence we have completed the proof by the induction argument.

The necessary condition is also proved by mathematical induction. The proposition is obviously true for $n = 1$. Assume that the proposition is true for $n = m$. It is sufficient to prove that, for all $x_j \leq t_j, j = 1, \dots, m$

$$F_{X_{m+1} | \bigcap_{j=1}^m X_j = x_j}(x_{m+1}) \geq F_{X_{m+1} | \bigcap_{j=1}^m X_j = t_j}(x_{m+1}). \quad (2)$$

If $\mathbf{t}_{m+1} \in R_{\mathbf{X}}(\mathbf{x})$, then, for $s = 1, \dots, m+1$, it is held that

$$t_s \geq F_{X_s | \bigcap_{j=1}^{s-1} X_j = t_j}^- [F_{X_s | \bigcap_{j=1}^{s-1} X_j = x_j}(x_s)].$$

In particular, if

$$t_{m+1} = F_{X_{m+1} | \bigcap_{j=1}^m X_j = t_j}^- [F_{X_{m+1} | \bigcap_{j=1}^m X_j = x_j}(x_m)],$$

given that $R_{\mathbf{X}}(\mathbf{x}) \subset C(\mathbf{x})$ for all $\mathbf{x} \in \mathbb{R}^n$, it holds that

$$F_{X_{m+1} | \bigcap_{j=1}^m X_j = t_j}^- [F_{X_{m+1} | \bigcap_{j=1}^m X_j = x_j}(x_m)] \geq x_{m+1}. \quad (3)$$

Now, from the fact that $F_{X_{m+1} | \bigcap_{j=1}^m X_j = x_j}(x)$ is an increasing function in x , by solving the inequality (3), the inequality (2) is obtained. \square

Theorem 2. \mathbf{X} is a CDS random vector if and only if $C(\mathbf{x}) \cap \text{Supp}(\mathbf{X}) \subset R_{\mathbf{X}}(\mathbf{x})$ for all $\mathbf{x} \in \mathbb{R}^n$

Proof. First, we prove the sufficient conditions. The proof will be obtained by mathematical induction. The proposition is obviously true for $n = 1$. Assume that the proposition is true for $n = m$. Now we need to show that it is true for $n = m + 1$. If $\mathbf{t}_{m+1} \in C(\mathbf{x}_{m+1}) \cap \text{Supp}(\mathbf{X})$, then $\mathbf{t}_{m+1} \geq \mathbf{x}_{m+1}$. Since \mathbf{X} is CDS, it follows that, for all $x_j \leq t_j, j = 1, \dots, m$

$$F_{X_{m+1} | \bigcap_{j=1}^m X_j = t_j}(x_{m+1}) \geq F_{X_{m+1} | \bigcap_{j=1}^m X_j = x_j}(x_{m+1}). \quad (4)$$

On the other hand, given that $F_{X_{m+1} | \bigcap_{j=1}^m X_j = t_j}(x)$ is increasing in x ,

$$F_{X_{m+1} | \bigcap_{j=1}^m X_j = t_j}(t_{m+1}) \geq F_{X_{m+1} | \bigcap_{j=1}^m X_j = t_j}(x_{m+1}). \quad (5)$$

From (4) and (5) it holds that

$$F_{X_{m+1} | \bigcap_{j=1}^m X_j = t_j}(t_{m+1}) \geq F_{X_{m+1} | \bigcap_{j=1}^m X_j = x_j}(x_{m+1}).$$

Given that $F_{X_{m+1} | \bigcap_{j=1}^m X_j = t_j}^-(u)$ is an increasing function in u , then

$$t_{m+1} \geq F_{X_{m+1} | \bigcap_{j=1}^m X_j = t_j}^- [F_{X_{m+1} | \bigcap_{j=1}^m X_j = x_j}(x_{m+1})].$$

Therefore, $\mathbf{t}_{m+1} \in R_{\mathbf{X}}(\mathbf{x})$.

The necessary condition is also proved by mathematical induction. The proposition is obviously true for $n = 1$. Assume that the proposition is true for $n = m$, then it is sufficient to prove that, for all $x_j \leq t_j, j = 1, \dots, m$, it holds

$$F_{X_{m+1} | \bigcap_{j=1}^m X_j = t_j}(x_{m+1}) \geq F_{X_{m+1} | \bigcap_{j=1}^m X_j = x_j}(x_{m+1}). \quad (6)$$

If $\mathbf{t}_{m+1} \in C(\mathbf{x}) \cap \text{Supp}(\mathbf{x}) \subset R_{\mathbf{X}}(\mathbf{x})$, then

$$t_s \geq F_{X_s | \bigcap_{j=1}^{s-1} X_j = t_j}^- [F_{X_s | \bigcap_{j=1}^{s-1} X_j = x_j}(x_s)]$$

and $t_s \geq x_s$, for $s = 1, \dots, m+1$. In particular, if $t_{m+1} = x_{m+1}$, it holds that

$$x_{m+1} \geq F_{X_{m+1} | \bigcap_{j=1}^m X_j = t_j}^- [F_{X_{m+1} | \bigcap_{j=1}^m X_j = x_j}(x_{m+1})],$$

and, given that $F_{X_{m+1} | \bigcap_{j=1}^m X_j = t_j}(x)$ is an increasing function in x , the inequality (6) is obtained. Thus, \mathbf{X} is CDS. \square

Now, the monotonicity of the $\widehat{\mathbf{x}}(\mathbf{u})$ is characterized by the CIS or CDS property of the distribution function of \mathbf{X} . Let $\phi_{\mathbf{X}} : [0, 1]^n \rightarrow \mathbb{R}^n$ be such that $\phi_{\mathbf{X}}(\mathbf{u}) = \widehat{\mathbf{x}}(\mathbf{u})$ and $\phi_{\mathbf{X}}^{-1}$ its corresponding inverse function.

Theorem 3. \mathbf{X} is a CIS random vector if and only if $\phi_{\mathbf{X}}$ is increasing.

Proof. For the sufficient condition, see Rubinstein *et al.* (1985).

The necessary condition will be by mathematical induction. From Theorem 1, it is sufficient to prove that $R_{\mathbf{X}}(\mathbf{x}) \subset C(\mathbf{x})$. The statement is obviously true for $n = 1$. Assume that the proposition is true for $n = m$. Let $\mathbf{t}_{m+1} \in R_{\mathbf{X}}(\mathbf{x})$, that is,

$$t_s \geq F_{X_s | \bigcap_{j=1}^{s-1} X_j = t_j}^- [F_{X_s | \bigcap_{j=1}^{s-1} X_j = x_j}(x_s)]$$

for $s = 1, \dots, m+1$. In particular, for $s = m+1$, it holds

$$t_{m+1} \geq F_{X_{m+1} | \bigcap_{j=1}^m X_j = t_j}^- [F_{X_{m+1} | \bigcap_{j=1}^m X_j = x_j}(x_{m+1})]$$

and, given that $F_{X_{m+1} | \bigcap_{j=1}^m X_j = t_j}(x)$ is increasing in x , it follows

$$F_{X_{m+1} | \bigcap_{j=1}^m X_j = t_j}(t_{m+1}) \geq F_{X_{m+1} | \bigcap_{j=1}^m X_j = x_j}(x_{m+1}).$$

Now, let $t_j = \widehat{x}(\mathbf{v}_j)$, $x_j = \widehat{x}(\mathbf{u}_j)$ for $j = 1, \dots, m$ and $v_{m+1} = F_{X_{m+1} | \bigcap_{j=1}^m X_j = t_j}(t_{m+1})$ and $u_{m+1} = F_{X_{m+1} | \bigcap_{j=1}^m X_j = x_j}(x_{m+1})$. Then, by the hypothesis, $\widehat{x}(\mathbf{v}_{m+1}) \geq \widehat{x}(\mathbf{u}_{m+1})$, that is

$$\begin{aligned} & F_{X_{m+1} | \bigcap_{j=1}^m X_j = \widehat{x}(\mathbf{v}_j)}^- [F_{X_{m+1} | \bigcap_{j=1}^m X_j = \widehat{x}(\mathbf{v}_j)}(t_{m+1})] \\ & \geq F_{X_{m+1} | \bigcap_{j=1}^m X_j = \widehat{x}(\mathbf{u}_j)}^- [F_{X_{m+1} | \bigcap_{j=1}^m X_j = \widehat{x}(\mathbf{u}_j)}(x_{m+1})]. \end{aligned}$$

Therefore, $t_{m+1} \geq x_{m+1}$ and the result is obtained. \square

Note that this theorem shows that the CIQ property, which was given in Belzunce *et al.* (2008), is equivalent to the CIS property. Thus, as a consequence, all the multivariate dispersive orders considered in Belzunce *et al.* (2008), are equivalent for CIS vectors having a common copula.

Theorem 4. \mathbf{X} is a CDS random vector if and only if $\phi_{\mathbf{X}}^{-1}$ is increasing.

Proof. Suppose that \mathbf{X} is a CDS random vector. The proof will be by mathematical induction. The proposition is obviously true for $n = 1$. Assume that the proposition is true for $n = m$. If \mathbf{X} is a CDS random vector, then

$$F_{X_{m+1}|\cap_{j=1}^m X_j=\widehat{\mathbf{x}}(\mathbf{u}_j)}^-(u_{m+1}) \geq F_{X_{m+1}|\cap_{j=1}^m X_j=\widehat{\mathbf{x}}(\mathbf{v}_j)}^-(u_{m+1}) \quad (7)$$

for all $\mathbf{u}_j \leq \mathbf{v}_j, j = 1, \dots, m$. If $\widehat{\mathbf{x}}(\mathbf{u}_{m+1}) \leq \widehat{\mathbf{x}}(\mathbf{v}_{m+1})$, then by definition

$$F_{X_{m+1}|\cap_{j=1}^m X_j=\widehat{\mathbf{x}}(\mathbf{u}_j)}^-(u_{m+1}) \leq F_{X_{m+1}|\cap_{j=1}^m X_j=\widehat{\mathbf{x}}(\mathbf{v}_j)}^-(v_{m+1}). \quad (8)$$

Finally, from (7) and (8) and given that $F_{X_{m+1}|\cap_{j=1}^m X_j=\widehat{\mathbf{x}}(\mathbf{v}_j)}^-(u)$ is increasing in u , it follows that $v_{m+1} \geq u_{m+1}$ and the result is obtained.

Conversely, suppose that $\widehat{\mathbf{x}}(\mathbf{u}_{m+1}) \leq \widehat{\mathbf{x}}(\mathbf{v}_{m+1})$ implies $\mathbf{u}_{m+1} \leq \mathbf{v}_{m+1}$. In the light of Theorem 2, it is sufficient to prove that $C(\mathbf{x}) \subset R_{\mathbf{X}}(\mathbf{x})$ for all $\mathbf{x} \in \mathbb{R}^m$.

Let $\mathbf{t}_{m+1} \in C(\mathbf{x})$, that is,

$$t_s \geq x_s \text{ for } s = 1, \dots, m+1. \quad (9)$$

In particular, for $s = m+1$ and from the regularity conditions, the inequality (9) is equivalent to $F_{X_{m+1}|\cap_{j=1}^m X_j=t_j}^-[F_{X_{m+1}|\cap_{j=1}^m X_j=t_j}(t_{m+1})] \geq F_{X_{m+1}|\cap_{j=1}^m X_j=x_j}^-[F_{X_{m+1}|\cap_{j=1}^m X_j=x_j}(x_{m+1})]$.

Now, if for $j = 1, \dots, m$ it is $t_j = \widehat{\mathbf{x}}(\mathbf{v}_j)$ and $x_j = \widehat{\mathbf{x}}(\mathbf{u}_j)$, and

$$\begin{aligned} v_{m+1} &= F_{X_{m+1}|\cap_{j=1}^m X_j=t_j}(t_{m+1}), \\ u_{m+1} &= F_{X_{m+1}|\cap_{j=1}^m X_j=x_j}(x_{m+1}), \end{aligned}$$

then the above inequality can be rewritten as

$$F_{X_{m+1}|\cap_{j=1}^m X_j=\widehat{\mathbf{x}}(\mathbf{v}_j)}^-(v_{m+1}) \geq F_{X_{m+1}|\cap_{j=1}^m X_j=\widehat{\mathbf{x}}(\mathbf{u}_j)}^-(u_{m+1}). \quad (10)$$

Moreover, by the hypothesis and the inequality (10), $v_{m+1} \geq u_{m+1}$ holds. Consequently, given that $F_{X_{m+1}|\cap_{j=1}^m X_j=t_j}(x)$ is increasing in x , it follows that

$$t_{m+1} \geq F_{X_{m+1}|\cap_{j=1}^m X_j=t_j}^-[F_{X_{m+1}|\cap_{j=1}^m X_j=x_j}(x_{m+1})].$$

Therefore, $\mathbf{t}_{m+1} \in R_{\mathbf{X}}(\mathbf{x})$ and the result is obtained. \square

3. The multivariate excess wealth function

In this section, the multivariate excess wealth function is defined following the same steps given for definition in the univariate case in Fernández-Ponce *et al.* (1996). One purpose is to generalize the univariate version and to prove that it preserves some similar properties.

Definition 3. Let \mathbf{X} be a nonnegative random vector. Then the multiple expectation associated to \mathbf{X} , when it exists, is defined as the real value

$$\bar{\mu}_{\mathbf{X}} = \int_{\text{Supp}(\mathbf{X})} P[\mathbf{X} \in R_{\mathbf{X}}(\mathbf{t})] dt.$$

Remark 2. Let $\mathbf{X} = (X_1, X_2)$ be a bivariate random variable. Then under straightforward calculations is easily obtained by using (1) that

$$\bar{\mu}_{\mathbf{X}} = \nu_{\mathbf{X}} - \int_{F_{X_1}^-(0)}^{+\infty} \bar{F}_1(t) F_{X_2|X_1=t}^-(0) dt,$$

where $\nu_{\mathbf{X}} = \int_{F_{X_1}^-(0)}^{+\infty} \bar{F}_1(t) \mathbf{E}[X_2|X_1=t] dt$. Particularly, if \mathbf{X} represents a non-negative lifetime random variable then

$$\bar{\mu}_{\mathbf{X}} \leq \nu_{\mathbf{X}}.$$

If $\text{Supp}(\mathbf{X}) = [0, +\infty)^2$, then $\bar{\mu}_{\mathbf{X}} = \nu_{\mathbf{X}}$ holds. Furthermore, if the components are independent random variables, then the multiple expectation coincides with the product of the marginal expectations.

The value of $\nu_{\mathbf{X}}$ in the bivariate case can be easily obtained if the first component has an exponential distribution. This fact is proved in the following proposition.

Proposition 2. Let $\mathbf{X} = (X_1, X_2)$ be a couple of random lifetimes, and let X_1 have an exponential distribution. Then $\nu_{\mathbf{X}} = \mathbf{E}[X_1] \cdot \mathbf{E}[X_2]$.

Proof. Given that X_1 has an exponential distribution, it holds that $X_1 =_{st} X_1^e$, where X_1^e is the lifetime having density function $f_{X_1^e}(t) = \bar{F}_{X_1}(t)/\mathbf{E}[X_1], t \geq 0$.

It can also be noted that $\mathbf{E}[X_2] = \int_0^{+\infty} \mathbf{E}[X_2|X_1=t] dF_{X_1}(t)$, so that

$$\int_0^{+\infty} (\mathbf{E}[X_2|X_1=t] - \mathbf{E}[X_2]) dF_{X_1}(t) = 0. \quad (11)$$

Now, let the function $\varphi(t)$ defined as $\varphi(t) = \mathbf{E}[X_2|X_1=t] - \mathbf{E}[X_2]$. By using (11), it holds that $\mathbf{E}[\varphi(X_1)] = 0$ and by taking into account that $X_1 =_{st} X_1^e$, it follows

$$\begin{aligned} 0 &= \mathbf{E}[\varphi(X_1)] = \mathbf{E}[\varphi(X_1^e)] \\ &= \int_0^{+\infty} (\mathbf{E}[X_2|X_1=t] - \mathbf{E}[X_2]) dF_{X_1^e}(t) \\ &= \int_0^{+\infty} (\mathbf{E}[X_2|X_1=t] - \mathbf{E}[X_2]) \frac{\bar{F}_{X_1}(t)}{\mathbf{E}[X_1]} dt. \end{aligned}$$

By using the previous inequality jointly with the fact that $\nu_{\mathbf{X}} = \int_0^{+\infty} \mathbf{E}[X_2|X_1=t] \bar{F}_{X_1}(t) dt$ and $\mathbf{E}[X_1] > 0$, it is immediately obtained that

$$\begin{aligned} \nu_{\mathbf{X}} &= \int_0^{+\infty} \mathbf{E}[X_2|X_1=t] \bar{F}_{X_1}(t) dt \\ &= \int_0^{+\infty} \mathbf{E}[X_2] \bar{F}_{X_1}(t) dt = \mathbf{E}[X_1] \mathbf{E}[X_2]. \end{aligned}$$

□ **4. The multivariate excess wealth ordering**

Definition 4. Let \mathbf{X} be a nonnegative random vector with finite multiple expectation. The multivariate excess wealth function associated to \mathbf{X} is defined as

$$S_{\mathbf{X}}^+(\mathbf{u}) = \int_{R_{\mathbf{X}}[\hat{\mathbf{x}}(\mathbf{u})]} P[\mathbf{X} \in R_{\mathbf{X}}(\mathbf{t})] d\mathbf{t}, \quad \mathbf{u} \in [0, 1]^n. \quad (12)$$

Several interesting properties for the multivariate excess function can be shown as in the univariate case.

Proposition 3. Let \mathbf{X} be a nonnegative random vector with finite multiple expectation. Then

- i) $S_{\mathbf{X}}^+(\mathbf{u})$ is a decreasing and a shift invariant function.
- ii) $0 \leq S_{\mathbf{X}}^+(\mathbf{u}) \leq S_{\mathbf{X}}^+(\mathbf{0}) = \bar{\mu}_{\mathbf{X}}$ for all \mathbf{u} in $[0, 1]^n$.
- iii) If the components of \mathbf{X} are independent, then

$$S_{\mathbf{X}}^+(\mathbf{u}) = \prod_{i=1}^n S_{X_i}^+(u_i).$$

Proof. Trivial and therefore omitted. □

Particularly, it is interesting to obtain an expression for the bivariate excess wealth function easier to hand. Let $\mathbf{X} = (X_1, X_2)$ be a bi-dimensional random vector satisfying the RC conditions with density function $f_{\mathbf{X}}(x_1, x_2)$. Obviously, it holds that

$$\hat{\mathbf{x}}(u_1, u_2) = (F_{X_1}^-(u_1), F_{X_2|X_1=F_{X_1}^-(u_1)}^-(u_2))$$

and $\mathbf{x} \in R_{\mathbf{X}}(\hat{\mathbf{x}}(u_1, u_2))$ if

$$x_1 \geq F_{X_1}^-(u_1) \text{ and } x_2 \geq F_{X_2|X_1=x_1}^-(u_2).$$

Consequently, by using (1) the bivariate excess wealth function can be expressed as

$$S_{\mathbf{X}}^+(u_1, u_2) = \int_{F_{X_1}^-(u_1)}^{\infty} \bar{F}_{X_1}(t_1) \cdot S_{X_2|X_1=t_1}^+(u_2) dt_1. \quad (13)$$

Differentiating (12), it is easily shown that

$$\frac{\partial S_{\mathbf{X}}^+(u_1, u_2)}{\partial u_2 \partial u_1} = \frac{P(\mathbf{X} \in R_{\mathbf{X}}[\hat{\mathbf{x}}(\mathbf{u})])}{f_{\mathbf{X}}(\hat{\mathbf{x}}(\mathbf{u}))} \quad (14)$$

for all (u_1, u_2) in $(0, 1)^2$.

In this section the multivariate excess wealth ordering is defined and some of its properties are proved.

Definition 5. Let \mathbf{X} and \mathbf{Y} be two nonnegative random vectors with finite multiple expectations. \mathbf{X} is said to be smaller than \mathbf{Y} in the sense of multivariate excess wealth order (denoted $\mathbf{X} \leq_{ew} \mathbf{Y}$) if

$$S_{\mathbf{X}}^+(\mathbf{u}) \leq S_{\mathbf{Y}}^+(\mathbf{u}) \text{ for all } \mathbf{u} \text{ in } (0, 1)^n.$$

Note that this ordering is the multivariate version of the excess wealth ordering which was studied in Shaked and Shanthikumar (1998) and Fernández-Ponce *et al.* (1998).

Example 1. Let \mathbf{X} and \mathbf{Y} have a bivariate Pareto distribution with parameters θ_1, θ_2, a and θ'_1, θ'_2, a' , respectively. If $2 < a' \leq a$ and $\theta_i \leq \theta'_i$ for $i = 1, 2$, then $\mathbf{X} \leq_{ew} \mathbf{Y}$.

In fact, if X has a joint Pareto density given by

$$f(t_1, t_2) = \frac{a(a+1)}{\theta_1 \theta_2} \left(\frac{t_1}{\theta_1} + \frac{t_2}{\theta_2} - 1 \right)^{-(a+2)},$$

with, $a > 0, t_i \geq \theta_i > 0$, easy calculations show that, for $t_i \geq \theta_i$,

$$\bar{F}_{X_2|X_1=t_1}(t_2) = \frac{t_1^{(a+1)}}{\theta_1^{(a+1)}} \left(\frac{t_1}{\theta_1} + \frac{t_2}{\theta_2} - 1 \right)^{-(a+1)}.$$

The excess-wealth function of $X_2|X_1 = t_1$ has the following expression:

$$\begin{aligned} S_{X_2|X_1=t_1}^+(u_2) &= \int_{F_{X_2|X_1=t_1}^-(u_2)}^{+\infty} \bar{F}_{X_2|X_1=t_1}(t_2) dt_2 \\ &= \int_{F_{X_2|X_1=t_1}^-(u_2)}^{+\infty} \frac{t_1^{(a+1)}}{\theta_1^{(a+1)}} \left(\frac{t_1}{\theta_1} + \frac{t_2}{\theta_2} - 1 \right)^{-(a+1)} dt_2 \\ &= \frac{t_1 \theta_2}{a \theta_1} (1 - u_2)^{\frac{a}{a+1}}. \end{aligned}$$

Therefore, by using (4), the bivariate excess-wealth for the vector \mathbf{X} is given by

$$\begin{aligned} S_{\mathbf{X}}(u_1, u_2) &= \int_{F_{X_1}^-(u_1)}^{+\infty} \bar{F}_{X_1}(t_1) S_{X_2|X_1=t_1}^+(u_2) dt_1 \\ &= \int_{F_{X_1}^-(u_1)}^{+\infty} \theta_1^a t_1^{-a} \frac{t_1 \theta_2}{a \theta_1} (1 - u_2)^{\frac{a}{a+1}} dt_1 \\ &= \frac{\theta_2 \theta_1 (1 - u_2)^{\frac{a}{a+1}} (1 - u_1)^{\frac{a-2}{a}}}{a(a-2)}, \end{aligned}$$

for $a > 2$. It is easily seen that the functions $h(a) = (1 - u_2)^{\frac{a}{a+1}} (1 - u_1)^{\frac{a-2}{a}}$ and $g(a) = \frac{1}{a(a-2)}$ are decreasing in a . So, for $2 < a' \leq a$ and $\theta_i \leq \theta'_i$ $i = 1, 2$, it follows that

$$\frac{\theta_2 \theta_1 (1 - u_2)^{\frac{a}{a+1}} (1 - u_1)^{\frac{a-2}{a}}}{a(a-2)} \leq \frac{\theta'_2 \theta'_1 (1 - u_2)^{\frac{a'}{a'+1}} (1 - u_1)^{\frac{a'-2}{a'}}}{a'(a'-2)},$$

that is, $\mathbf{X} \leq_{ew} \mathbf{Y}$.

It is easy to prove the following closure results. The notation \sim_{ew} means that both $\mathbf{X} \leq_{ew} \mathbf{Y}$ and $\mathbf{Y} \leq_{ew} \mathbf{X}$ hold.

Theorem 5. i) Let $\mathbf{X}^{(1)}, \dots, \mathbf{X}^{(m)}$ be a set of independent random vectors and let $\mathbf{Y}^{(1)}, \dots, \mathbf{Y}^{(m)}$ be another set of independent random vectors. If $\mathbf{X}^{(i)} \leq_{ew} \mathbf{Y}^{(i)}$ for $i = 1, \dots, m$, then $(\mathbf{X}^{(1)}, \dots, \mathbf{X}^{(m)}) \leq_{ew} (\mathbf{Y}^{(1)}, \dots, \mathbf{Y}^{(m)})$.

ii) Let $\{\mathbf{X}^{(j)} : j = 1, 2, \dots\}$ and $\{\mathbf{Y}^{(j)} : j = 1, 2, \dots\}$ be two sequences of random vectors such that $\mathbf{X}^{(j)} \rightarrow_{st} \mathbf{X}$ and $\mathbf{Y}^{(j)} \rightarrow_{st} \mathbf{Y}$ as $j \rightarrow \infty$, where \rightarrow_{st} denotes convergence in distribution. If $\mathbf{X}^{(j)} \leq_{ew} \mathbf{Y}^{(j)}$ for every $j = 1, 2, \dots$, then $\mathbf{X} \leq_{ew} \mathbf{Y}$.

Proof. i) It is trivial by using Definition 5 and iii) of the Proposition 3.

ii) It is easy to show that if $\mathbf{X}^{(j)} \rightarrow_{st} \mathbf{X}$ then $\hat{\mathbf{x}}^{(j)}(\mathbf{u}) \rightarrow \hat{\mathbf{x}}(\mathbf{u})$ and $R_{\mathbf{X}^{(j)}}[\hat{\mathbf{x}}^{(j)}(\mathbf{u})] \rightarrow R_{\mathbf{X}}[\hat{\mathbf{x}}(\mathbf{u})]$ for all \mathbf{u} in $(0, 1)^n$. Now by using the monotone convergence theorem and the fact that $\bar{\mu}_{\mathbf{X}^{(j)}} < +\infty$ for all j , it is easily shown that $S_{\mathbf{X}^{(j)}}^+(\mathbf{u}) \rightarrow S_{\mathbf{X}}^+(\mathbf{u})$. Thus the result is immediately obtained. \square

Some properties and results of the excess wealth order are proved for the bivariate case. These properties can be easily generalized to any dimension.

Theorem 6. Let $\mathbf{X} = (X_1, X_2)$ and $\mathbf{Y} = (Y_1, Y_2)$ be two random vectors.

1. If $\mathbf{X} \sim_{st} \mathbf{Y} + \mathbf{c}$ then $\mathbf{X} \sim_{ew} \mathbf{Y}$.
2. If $\mathbf{X} \sim_{ew} \mathbf{Y}$ then $f[\hat{\mathbf{x}}(\mathbf{u})] = g[\hat{\mathbf{y}}(\mathbf{u})]$ for all \mathbf{u} in $(0, 1)^2$, where $f(\cdot)$ and $g(\cdot)$ are the corresponding density functions for \mathbf{X} and \mathbf{Y} , respectively.

Proof. (1) Trivial, since the multivariate excess wealth function is shift invariant, as it can be easily verified.

(2) Suppose $\mathbf{X} \sim_{ew} \mathbf{Y}$, i.e., suppose it holds

$$S_{\mathbf{X}}^+(\mathbf{u}) = S_{\mathbf{Y}}^+(\mathbf{u}) \text{ for all } \mathbf{u} \text{ in } (0, 1)^2.$$

Since \mathbf{X} and \mathbf{Y} satisfy the regularity conditions, it follows that the quantiles $\hat{\mathbf{x}}(\mathbf{u})$ and $\hat{\mathbf{y}}(\mathbf{u})$ are differentiable with respect to $\mathbf{u} = (u_1, u_2)$ at each component. Consequently, by using (14) and Proposition 1, it is immediately obtained the result. \square

A multivariate dispersion ordering based on the standard construction was given by Fernández-Ponce and Suárez-Lloréns (2003). Given two n -dimensional random vectors \mathbf{X} and \mathbf{Y} , we say that \mathbf{X} is smaller than \mathbf{Y} in the multivariate dispersion order, denoted by $\mathbf{X} \leq_{disp} \mathbf{Y}$, if, and only if,

$$\|\hat{\mathbf{x}}(\mathbf{v}) - \hat{\mathbf{x}}(\mathbf{u})\|_2 \leq \|\hat{\mathbf{y}}(\mathbf{v}) - \hat{\mathbf{y}}(\mathbf{u})\|_2,$$

for all $\mathbf{u}, \mathbf{v} \in [0, 1]^n$, where $\|\cdot\|_2$ means the Euclidean distance.

Fernández-Ponce and Suárez-Lloréns (2003) established that the multivariate dispersion ordering is characterized by an unique expansion function which maps each quantile for one variable in the corresponding quantile for the other one. Particularly, Arias-Nicolás *et al.* (2005) studied the concept of multivariate dispersion order for multivariate distributions with the same dependence structure. Later on, Belzunce *et al.* (2008) studied a weaker multivariate dispersion ordering defined as \mathbf{X} is said to be less in the conditional dispersive order than \mathbf{Y} , denoted by $\mathbf{X} \leq_{c-disp} \mathbf{Y}$, if, and only if,

$$X_1 \leq_{disp} Y_1, \\ X_i | \bigcap_{j=1}^{i-1} X_j = \hat{x}_j(\mathbf{u}_j) \leq_{disp} Y_i | \bigcap_{j=1}^{i-1} Y_j = \hat{y}_j(\mathbf{u}_j).$$

Now, it is proved that the multivariate conditional dispersion ordering implies the excess wealth ordering.

Theorem 7. Let \mathbf{X} and \mathbf{Y} be two absolutely continuous random vectors. If $\mathbf{X} \leq_{c-disp} \mathbf{Y}$ then $\mathbf{X} \leq_{ew} \mathbf{Y}$.

Proof. For simplicity, the bidimensional case is proved. This proof can easily be generalized to any dimension. By using the equality (1), the bivariate excess-wealth function of \mathbf{X} can be expressed as

$$S_{\mathbf{X}}^+(\mathbf{u}) = \int_{F_{X_1}^-(u_1)}^{\infty} \int_{F_{X_2|X_1=t_1}^-(u_2)}^{\infty} \bar{F}_{X_1}(t_1) \bar{F}_{X_2|X_1=t_1}(t_2) dt_1 dt_2.$$

By taking $w_1 = F_{X_1}(t_1)$ and $w_2 = F_{X_2|X_1=t_1}(t_2)$, it follows that

$$S_{\mathbf{X}}^+(\mathbf{u}) = \int_{u_1}^1 \int_{u_2}^1 \frac{(1-w_1)(1-w_2)}{f_{\mathbf{X}}(\hat{\mathbf{x}}(\mathbf{w}))} dw_1 dw_2$$

where $f_{\mathbf{X}}(\cdot)$ is the density function of \mathbf{X} . Similarly,

$$S_{\mathbf{Y}}^+(\mathbf{u}) = \int_{u_1}^1 \int_{u_2}^1 \frac{(1-w_1)(1-w_2)}{f_{\mathbf{Y}}(\hat{\mathbf{y}}(\mathbf{w}))} dw_1 dw_2$$

where $f_{\mathbf{Y}}(\cdot)$ is the density function of \mathbf{Y} .

It is clear that if $\mathbf{X} \leq_{c-disp} \mathbf{Y}$, then $f_{\mathbf{X}}(\hat{\mathbf{x}}(\mathbf{w})) \geq f_{\mathbf{Y}}(\hat{\mathbf{y}}(\mathbf{w})) \quad \forall \mathbf{w} \in [0, 1]^2$ (see Belzunce *et al.*, 2008).

Therefore, the result is immediately obtained. \square

An example where two random vectors are ordered in excess wealth, but not in multivariate dispersion sense, is given here.

Example 2. Suppose that $\mathbf{X} = (X_1, X_2)$ is a bivariate exponential random vector such that X_1 and X_2 are independent, $X_1 \sim_{st} \text{Exp}(2)$ and $X_2 \sim_{st} \text{Exp}(1)$. Similarly, assume that $\mathbf{Y} = (Y_1, Y_2)$ is a bivariate exponential random vector such that Y_1 and Y_2 are independent with $Y_1 \sim_{st} \text{Exp}(1/3)$ and $Y_2 \sim_{st} \text{Exp}(3)$. Consequently, it holds that

$$X_1 <_{disp} Y_1 \text{ and } Y_2 <_{disp} X_2$$

which implies that $\mathbf{X} \not\prec_{c-disp} \mathbf{Y}$. Furthermore, by using **iii**) of Proposition 3, it holds

$$\begin{aligned} S_{\mathbf{X}}^+(u_1, u_2) &= \frac{1}{2}(1-u_1)(1-u_2) \\ &\leq (1-u_1)(1-u_2) = S_{\mathbf{Y}}^+(u_1, u_2) \end{aligned}$$

for all (u_1, u_2) in $(0, 1)^2$, i.e. $\mathbf{X} \leq_{ew} \mathbf{Y}$.

The following result describes conditions under which the multivariate excess wealth order holds. Some previous definitions are necessary. Let X and Y be two univariate random variables with excess wealth function $S_X^+(u)$ and $S_Y^+(u)$, respectively.

Definition 6. Let X and Y be two univariate random variables. X is said to be smaller than Y in relative excess wealth sense (denoted $X \leq_{rew} Y$) if

$$\frac{S_X^+(v)}{S_X^+(u)} \leq \frac{S_Y^+(v)}{S_Y^+(u)} \text{ for all } 0 < u \leq v \leq 1.$$

Note that, when the supports of X and Y are $[0, +\infty)$, this ordering is equivalent to the DMRL ordering which was defined in Kochar and Wiens (1987) and further characterized in Fernández-Ponce, *et al.* (1996).

Definition 7. Let X and Y be two univariate random variables. X is said to be smaller than Y in wealth sense (denoted $X \leq_W Y$) if

$$X \leq_{ST} Y \text{ and } X \leq_{rew} Y.$$

Definition 8. Let $\mathbf{X} = (X_1, X_2)$ be a bidimensional random vector. \mathbf{X} is said to be conditional increasing in excess wealth ($\mathbf{X} \in \text{CIEW}$) if

$$X_2|X_1 = t_1 \leq_{ew} X_2|X_1 = t_2 \text{ for all } t_1 \leq t_2.$$

Recall that a distribution function F is said to be of power-law tail or Pareto type tail if, for $x \rightarrow +\infty$,

$$1 - F(x) \sim Kx^{-\mu},$$

where K is a positive normalization constant or a slowly varying function. The exponent $\mu > 0$ is called the tail exponent of the distribution.

Proposition 4. Let $\mathbf{X} = (X_1, X_2)$ be a bidimensional random vector. If $\frac{dF_{X_2|X_1=t}^-(u)}{dt}$ is an increasing function in u and $X_2|X_1 = t$ is a power-law tail with exponent equals to one, for all t , then $\mathbf{X} \in \text{CIEW}$.

Proof. By using an expression for the right-spread function which can be seen in Fernández-Ponce *et al.* (1996), it is easy to obtain that

$$S_{\mathbf{X}}^+(u) = \int_u^1 (1-\omega) dF_{\mathbf{X}}^-(\omega).$$

Now, integrating by parts and using the fact that the random variable $X \sim_{ST} X_2|X_1 = t$ is a power-law tail with exponent equals to one, it is held

$$\frac{dS_{X_2|X_1=t}^+(u)}{dt} = \int_u^1 \left(\frac{dF_{X_2|X_1=t}^-(\omega)}{dt} - \frac{dF_{X_2|X_1=t}^-(u)}{dt} \right) d\omega.$$

and the result is immediately obtained. \square

Theorem 8. Let $\mathbf{X} = (X_1, X_2)$ and $\mathbf{Y} = (Y_1, Y_2)$ be two bidimensional random vectors. If it is held that

- i) $X_1 \leq_W Y_1$,
- ii) $X_2|X_1 = t \leq_{ew} Y_2|Y_1 = t$ for all $t \in \mathbb{R}$,
- iii) $\mathbf{X} \in \text{CIEW}$ or $\mathbf{Y} \in \text{CIEW}$

then $\mathbf{X} \leq_{ew} \mathbf{Y}$.

Proof. Assume that $\mathbf{Y} \in \text{CIEW}$. By using (ii), it is obtained that

$$S_{\mathbf{X}}^+(u_1, u_2) \leq \int_{F_1^-(u_1)}^{\infty} \bar{F}_1(t) S_{Y_2|Y_1=t}^+(u_2) dt.$$

Now, consider the density functions

$$\tilde{f}_1(t) = \frac{\bar{F}_1(t)}{S_{X_1}^+(u_1)} I(t \geq F_{X_1}^-(u_1))$$

and

$$\tilde{g}_1(t) = \frac{\bar{G}_1(t)}{S_{Y_1}^+(u_1)} I(t \geq F_{Y_1}^-(u_1)).$$

The corresponding distribution functions are

$$\tilde{F}_1(x) = \left(1 - \frac{S_{X_1}^+(F_1(x))}{S_{X_1}^+(u_1)} \right) I(t \geq F_{X_1}^-(u_1))$$

and

$$\tilde{G}_1(x) = \left(1 - \frac{S_{Y_1}^+(G_1(x))}{S_{Y_1}^+(u_1)} \right) I(t \geq F_{Y_1}^-(u_1)).$$

By taking into account (i), we obtain that $\tilde{F}_1 \leq_{ST} \tilde{G}_1$. Thus,

$$\begin{aligned} \int_0^\infty S_{X_1}^+(u_1)S_{Y_2|Y_1=t}^+(u_2)d\tilde{F}_1(t) &\leq \\ \int_0^\infty S_{Y_1}^+(u_1)S_{Y_2|Y_1=t}^+(u_2)d\tilde{G}_1(t) &= S_{\mathbf{Y}}^+(u_1, u_2) \end{aligned}$$

and the result is obtained. The statement can be shown in a similar manner if $\mathbf{X} \in \text{CIEW}$ is assumed. \square

Example 3. Assume that X_1 and X_2 are independent random variables with exponential distributions whose means are equal to λ_1 (i.e. $X_i \sim \text{Exp}(\lambda_1)$ for $i = 1, 2$). Now, let Y_1 and Y_2 be two random variables such that

$$Y_1 \sim \text{Exp}(\lambda_2) \text{ and } Y_2|Y_1 = t \sim \text{Exp}(\lambda_2(t+1)) \quad \lambda_1 \leq \lambda_2.$$

It is easy to verify that the random vectors $\mathbf{X} = (X_1, X_2)$ and $\mathbf{Y} = (Y_1, Y_2)$ verify the conditions of Theorem 8. Consequently, $\mathbf{X} \leq_{ew} \mathbf{Y}$.

The following result describes some necessary conditions for the excess wealth order. An immediate application, dealing with conditions for comparisons in dependence sense of random vectors, will be given next. For the statement of this result, we recall the definition of the IGFR property. Let X be a nonnegative random variable with density function f_X , survival function \bar{F}_X and failure rate function $r(x) = f_X(x)/\bar{F}_X(x)$. The generalized failure rate is defined as $R(X) = xr(x)$. If the function $R(x)$ in increasing in x , then it is said that X has an increasing generalized failure rate (IGFR) distribution (the DGFR property can be defined analogously). Clearly, if X has increasing failure rate then it is also IGFR. However, the reversed need not hold, given that there exist many distributions having decreasing failure rate which are IGFR (See Belzunce *et al.*, 1998, and Lariviere, 2006). Also, recall that if \mathbf{X} is a random vector then its centered random vector is $\tilde{\mathbf{X}} = \mathbf{X} - E(\mathbf{X})$.

Theorem 9. Let $\mathbf{X} = (X_1, X_2)$ and $\mathbf{Y} = (Y_1, Y_2)$ be two bidimensional random vectors and $\tilde{\mathbf{X}}$ and $\tilde{\mathbf{Y}}$ their corresponding centered random vectors. If it is held that

- i) $X_1 \sim_{ST} Y_1$,
- ii) X_1 has a IGFR distribution,
- iii) $\text{Supp}(\tilde{\mathbf{X}}) \subseteq \text{Supp}(\tilde{\mathbf{Y}})$,
- iv) $\mathbf{X} \leq_{ew} \mathbf{Y}$,

then $\text{cov}(X_1, X_2) \leq \text{cov}(Y_1, Y_2)$.

Proof. For an easier notation, $F_1(\cdot)$ is used to denote $F_{X_1}(\cdot)$ and $F_{Y_1}(\cdot)$. Assume first that $E(X_2) = E(Y_2)$. By taking into account that

$$S_{\mathbf{X}}^+(u, 0) = \int_{F_1^-(u)}^{+\infty} \bar{F}_1(t) \left(E(X_2|X_1 = t) - F_{X_2|X_1=t}^-(0) \right) dt,$$

and a similar formula is held for the random vector \mathbf{Y} , by using (iv) it can be obtained the following inequality

$$\begin{aligned} \int_{F_1^-(u)}^{+\infty} \bar{F}_1(t) (E(Y_2|Y_1 = t) - E(X_2|X_1 = t)) dt - \\ \int_{F_1^-(u)}^{+\infty} \bar{F}_1(t) \left(F_{Y_2|Y_1=t}^-(0) - F_{X_2|X_1=t}^-(0) \right) dt \geq 0. \end{aligned}$$

By using (iii) is immediately obtained that

$$F_{Y_2|Y_1=t}^-(0) - F_{X_2|X_1=t}^-(0) \geq 0 \text{ for all } t \in \mathbb{R}.$$

Consequently,

$$\int_{F_1^-(u)}^{+\infty} \bar{F}_1(t) (E(Y_2|Y_1 = t) - E(X_2|X_1 = t)) dt \geq 0, \quad \forall u.$$

Let $dW(t) = \bar{F}_1(t) \frac{f_1(t)}{\bar{F}_1(t)} (E(Y_2|Y_1 = t) - E(X_2|X_1 = t)) dt$ and $h(t) = t \cdot \frac{f_1(t)}{\bar{F}_1(t)}$. By assumption (ii), $h(t)$ is increasing, and, by inequality above, $\int_s^{+\infty} dW(t) \geq 0$ for all $s = F_1^-(u) \geq 0$.

Now, using Lemma 7.1 (a) in Barlow and Proschan (1975), it is obtained that

$$\begin{aligned} \int_0^{+\infty} h(t) dW(t) = \\ \int_0^{+\infty} \bar{F}_1(t) \frac{f_1(t)}{\bar{F}_1(t)} t (E(Y_2|Y_1 = t) - E(X_2|X_1 = t)) dt = \\ \int_0^{+\infty} f_1(t) (E(tY_2|Y_1 = t) - E(tX_2|X_1 = t)) dt \geq 0. \end{aligned}$$

Thus,

$$E(Y_1 Y_2) \geq E(X_1 X_2)$$

and by (i) and (ii) the result holds. Now, assume that $E(X_2) \neq E(Y_2)$. Note that $\mathbf{X} \leq_{ew} \mathbf{Y}$ if, and only if $\tilde{\mathbf{X}} \leq_{ew} \tilde{\mathbf{Y}}$. Thus, in a similar manner, it is obtained that

$$E(X_1 \tilde{X}_2) \leq E(Y_1 \tilde{Y}_2),$$

and the result is immediately obtained. \square

The following corollary points out that, under appropriate assumption on aging for the first component, the excess wealth order can be considered as positive dependence order, since it implies the comparison between the covariances for vectors in the same Frechet class.

Corollary 1. Let $\mathbf{X} = (X_1, X_2)$ and $\mathbf{Y} = (Y_1, Y_2)$ be two bidimensional random vectors having the same marginal distributions. If X_1 has a IGFR distribution, then

$$\mathbf{X} \leq_{ew} \mathbf{Y} \Rightarrow \text{cov}(X_1, X_2) \leq \text{cov}(Y_1, Y_2).$$
