(Communicated by Bernold Fiedler)

Abstract. We analyze the existence of almost periodic (respectively, almost automorphic, recurrent) solutions of a linear non-homogeneous differential (or difference) equation in a Banach space, with almost periodic (respectively, almost automorphic, recurrent) coefficients. Under some conditions we prove that one of the following alternatives is fulfilled:
(i) There exists a complete trajectory of the corresponding homogeneous equation with constant positive norm;
(ii) The trivial solution of the homogeneous equation is uniformly asymptotically stable.
If the second alternative holds, then the non-homogeneous equation with almost periodic (respectively, almost automorphic, recurrent) coefficients possesses a unique almost periodic (respectively, almost automorphic, recurrent) solution. We investigate this problem within the framework of general linear nonautonomous dynamical systems. We apply our general results also to the cases of functional-differential equations and difference equations.

1. Introduction. Let \((X, \rho)\) be a complete metric space, \(\mathbb{R} (\mathbb{Z})\) be the group of real (integer) numbers. By \(\mathbb{S}\) we will denote either \(\mathbb{R}\) or \(\mathbb{Z}\) and by \(\mathbb{T}\) a sub-semigroup of \(\mathbb{S}\).

Let \((X, \pi)\) be a dynamical system on \(X\), i.e., let \(\pi : \mathbb{T} \times X \to X\) be a continuous function such that \(\pi(0, x) = x\) for all \(x \in X\), and \(\pi(t_1 + t_2, x) = \pi(t_2, \pi(t_1, x))\), for all \(x \in X\), and \(t_1, t_2 \in \mathbb{T}\).

Given \(\varepsilon > 0\), a number \(\tau \in \mathbb{T}\) is called an \(\varepsilon\)-shift (respectively, an \(\varepsilon\)-almost period) of \(x\), if \(\rho(\pi(\tau, x), x) < \varepsilon\) (respectively, \(\rho(\pi(\tau + t, x), \pi(t, x)) < \varepsilon\) for all \(t \in \mathbb{T}\)).

An \(m\)-dimensional torus is denoted by \(\mathbb{T}^m := \mathbb{R}^m / 2\pi \mathbb{Z}\). Let \((\mathbb{T}^m, \mathbb{T}, \sigma)\) be an irrational winding of \(\mathbb{T}^m\), i.e., \(\sigma(t, \nu) := (\nu_1 t, \nu_2 t, \ldots, \nu_m t)\) for all \(t \in \mathbb{S}\) and \(\nu \in \mathbb{T}^m\) and the numbers \(\nu_1, \nu_2, \ldots, \nu_m\) are rationally independent.

A point \(x \in X\) is called quasi-periodic with frequency \(\nu := (\nu_1, \nu_2, \ldots, \nu_m) \in \mathbb{T}^m\), if there exists a continuous function \(\Phi : \mathbb{T}^m \to X\) such that \(\pi(t, x) := \Phi(\sigma(t, \nu))\) for

2010 Mathematics Subject Classification. 34G10, 34K06, 34K14, 37B20, 37B25, 37B55, 37C75, 37L15, 37L30, 39A05, 39A24, 93D20.

Key words and phrases. Almost periodic solution, almost automorphic solutions, uniform asymptotic stability, nonautonomous dynamical systems, cocycle, linear nonautonomous contractive dynamical systems.
all \( t \in \mathbb{T} \), where \((T^m, \mathbb{T}, \sigma)\) is an irrational winding of the torus \( T^m \) and \( \omega \in T^m \). A point \( x \in X \) is called almost recurrent (respectively, Bohr almost periodic), if for any \( \varepsilon > 0 \) there exists a positive number \( l \) such that, in any segment of length \( l \), there is an \( \varepsilon \)-shift (respectively, an \( \varepsilon \)-almost period) of the point \( x \in X \).

If the point \( x \in X \) is almost recurrent, and the set \( H(x) := \{ \pi(t, x) \mid t \in \mathbb{T} \} \) is compact, then \( x \) is called recurrent, where the bar denotes the closure in \( X \).

Denote by \( \mathfrak{R}_x := \{ \{ t_n \} \subset \mathbb{T} : \text{ such that } \{ \pi(t_n, x) \} \to x \text{ and } \{ t_n \} \to \infty \} \).

A point \( x \in X \) is said to be Levitan almost periodic (see [11, 16]) for the dynamical system \((X, \mathbb{T}, \pi)\) if there exists a dynamical system \((Y, \mathbb{T}, \lambda)\), and a Bohr almost periodic point \( y \in Y \) such that \( \mathfrak{R}_y \subseteq \mathfrak{R}_x \).

**Remark 1.** Let \( x_i \in X_i \) \((i = 1, 2, \ldots, m)\) be a Levitan almost periodic point of the dynamical system \((X_i, \mathbb{T}, \pi_i)\). Then, the point \( x := (x_1, x_2, \ldots, x_m) \in X := X_1 \times X_2 \times \cdots \times X_m \) is also Levitan almost periodic for the product dynamical system \((X, \mathbb{T}, \pi)\), where \( \pi : \mathbb{T} \times X \to X \) is defined by the equality \( \pi(t, x) := (\pi_1(t, x_1), \pi_2(t, x_2), \ldots, \pi_m(t, x_m)) \) for all \( t \in \mathbb{T} \) and \( x := (x_1, x_2, \ldots, x_m) \in X \).

A point \( x \in X \) is called stable in the sense of Lagrange (st.L), if its trajectory \( \{ \pi(t, x) : t \in \mathbb{T} \} \) is relatively compact.

A point \( x \in X \) is called almost automorphic (see [16, 27]) for the dynamical system \((X, \mathbb{T}, \pi)\), if the following conditions hold:

(i) \( x \) is st.L;
(ii) There exists a dynamical system \((Y, \mathbb{T}, \lambda)\), a homomorphism \( h \) from \((X, \mathbb{T}, \pi)\) onto \((Y, \mathbb{T}, \lambda)\) and an almost periodic (in the sense of Bohr) point \( y \in Y \) such that \( h^{-1}(y) = \{ x \} \).

**Remark 2.** The following facts hold true.
1. Every almost periodic (respectively, almost automorphic) point is almost automorphic (respectively, recurrent), but inversely is not true.
2. Every almost automorphic point \( x \in X \) is also Levitan almost periodic.
3. A Levitan almost periodic point \( x \) with relatively compact trajectory \( \{ \pi(t, x) : t \in \mathbb{T} \} \) is also almost automorphic (see [1]–[5], [13], [17] and [27]). In other words, a Levitan almost periodic point \( x \) is almost automorphic, if and only if its trajectory \( \{ \pi(t, x) : t \in \mathbb{T} \} \) is relatively compact.
4. Let \((X, \mathbb{T}, \pi)\) and \((Y, \mathbb{T}, \lambda)\) be two dynamical systems, \( x \in X \), and assume that the following conditions are fulfilled:
   (i) there exists a point \( y \in Y \) which is Levitan almost periodic;
   (ii) \( \mathfrak{N}_y \subseteq \mathfrak{N}_x \).

Then, the point \( x \) is also Levitan almost periodic.
4. Let \( x \in X \) be a st.L point, \( y \in Y \) an almost automorphic point, and \( \mathfrak{N}_y \subseteq \mathfrak{N}_x \). Then, the point \( x \) is almost automorphic too.

We recall below a general method for the construction of dynamical systems on the space of continuous functions. In this way we will obtain many well-known dynamical systems on functional spaces (see, for example, [5, 23]). Let \((X, \mathbb{T}, \pi)\) be a dynamical system on \( X \), \( Y \) be a complete pseudo metric space, and \( P \) be a family of pseudo metrics on \( Y \). We denote by \( C(X, Y) \) the family of all continuous functions \( f : X \to Y \) equipped with the compact-open topology. This topology is given by the following family of pseudo metrics \( \{ d^K_p \} \) \((p \in P, \ K \in \mathcal{K}(X))\), where

\[
d^K_p(f, g) := \sup_{x \in K} p(f(x), g(x)),
\]
and $\mathcal{K}(X)$ denotes the family of all compact subsets of $X$. For all $\tau \in \mathbb{T}$ we define a mapping $\sigma_\tau : C(X,Y) \to C(X,Y)$ by the following equality: $(\sigma_\tau f)(x) := f(\pi(\tau, x))$, $x \in X$. We note that the family of mappings $\{\sigma_\tau : \tau \in \mathbb{T}\}$ possesses the next properties:

1. $\sigma_0 = Id_{C(X,Y)}$;
2. $\forall \tau_1, \tau_2 \in \mathbb{T}$, $\sigma_{\tau_1} \circ \sigma_{\tau_2} = \sigma_{\tau_1 + \tau_2}$;
3. $\forall \tau \in \mathbb{T}$, the mapping $\sigma_\tau : C(X,Y) \to C(X,Y)$ is continuous.

It is well-known (see [10]) that the triple $(C(X,Y), \mathbb{T}, \sigma)$, where $\sigma$ is defined by the equality $\sigma(\tau, f) := \sigma_\tau f$, $(f \in C(X,Y), \tau \in \mathbb{T})$, is a dynamical system.

Consider now a dynamical system given in the form of $(C(X,Y), \mathbb{T}, \sigma)$, and which is useful in the applications. Let $X = \mathbb{T}$, and denote by $(X, \mathbb{T}, \pi)$ a dynamical system on $\mathbb{T}$, where $\pi(t, x) := x + t$. The dynamical system $(C(T,Y), \mathbb{T}, \sigma)$ is called \textit{Bebutov's dynamical system} (a dynamical system of translations, or shifts dynamical system) (see [23]). For example, the equality

$$
d(f,g) := \sup_{L>0} \max \{d_L(f,g), L^{-1}\},
$$

where $d_L(f,g) := \max_{|t| \leq L} \rho(f(t), g(t))$, defines a complete metric (Bebutov's metric) on the space $C(T,Y)$ which is compatible with the compact-open topology on $C(T,Y)$.

The function $\varphi \in C(T,Y)$ is said to possess a property $(P)$, if the motion $\sigma(\cdot, \varphi) : \mathbb{T} \to C(T,Y)$ possesses this property in the Bebutov dynamical system $(C(T,Y), \mathbb{T}, \sigma)$, generated by the function $\varphi$. As property $(P)$ we can take periodicity, quasi-periodicity, almost periodicity, almost automorphy, recurrence, etc.

In this paper we investigate the existence of almost periodic (respectively, almost automorphic, recurrent) solutions of some linear differential equations in a Banach space with almost periodic (respectively, almost automorphic, jointly recurrent) coefficients of the form

$$
u'(t) + A(\sigma(t,y))u(t) = f(\sigma(t,y)), \quad (y \in Y),
$$

where $Y$ is a compact metric space, and $(Y, \mathbb{R}, \sigma)$ is a dynamical system on $Y$. We suppose that the following conditions hold:

1. $Y$ is a compact minimal set (i.e., every trajectory $\{\sigma(t,y) : t \in \mathbb{R}\}$ is dense in $Y$), and $y$ is an almost periodic (respectively, almost automorphic, recurrent) point;
2. $f \in C(Y,E)$, where $E$ is a Banach space with norm $|\cdot|$, and $C(Y,E)$ denotes the Banach space of continuous functions $f : Y \to E$ equipped with the norm $||f|| := \max_{y \in Y} |f(y)|$;
3. $A \in C([E])$, where $[E]$ is the Banach space of all linear bounded operators acting on the space $E$ and furnished with the operator norm

$$
||A|| := \sup_{x \in E, ||x|| \leq 1} |Ax|;
$$

4. $A(y)$ is self-adjoint for all $y \in Y$;
5. $A(y)$ is dissipative (i.e., $A(y) \geq 0$) for all $y \in Y$.

For finite-dimensional systems (i.e., $E = \mathbb{R}^n$), the problem

$$
u'(t) + A(t)u(t) = f(t)
$$

(2)
with almost periodic coefficients was studied by Cieutat and Haraux in [12], where the following results were established.

**Theorem 1.1.** (See [12]) Assume that $A : \mathbb{R} \to [\mathbb{R}^n]$ is a continuous almost periodic operator-valued function, such that, for all $t \in \mathbb{R}$, $A(t)$ is symmetric and $A(t) \geq 0$. If the average matrix

$$M(A) := \lim_{T \to +\infty} \frac{1}{2T} \int_{-T}^{T} A(s)ds$$

is positive definite (i.e., $\text{Ker} M(A) = \{0\}$), then, for each almost periodic forcing term $f : \mathbb{R} \to \mathbb{R}^n$, there exists a unique, exponentially stable almost periodic solution $u$ of (2).

Recall (see [12]) that a process on $\mathbb{R}^n$ is a two-parameter family of maps $U(t, \tau) : \mathbb{R}^n \to \mathbb{R}^n$, defined for $(t, \tau) \in \mathbb{R} \times \mathbb{R}^+$ (notice that $t$ represents the initial time and $\tau$ the elapsed one), and satisfying

(i) $\forall t \in \mathbb{R}, \forall x \in \mathbb{R}^n, U(t, 0)x = x$;
(ii) $\forall (t, s, \tau) \in \mathbb{R} \times \mathbb{R}^+ \times \mathbb{R}^+, \forall x \in \mathbb{R}^n, U(t, s + \tau) = U(t, s)U(t, \tau)$;
(iii) $\forall \tau \in \mathbb{R}^+$, the one-parameter family of maps $U(t, \tau) : \mathbb{R}^n \to \mathbb{R}^n$ with parameter $t \in \mathbb{R}$ is equicontinuous.

A process $U$ on $\mathbb{R}^n$ is said to be contractive if $|U(t, \tau)x_1 - U(t, \tau)x_2| \leq |x_1 - x_2|$ for all $(t, \tau) \in \mathbb{R} \times \mathbb{R}^+, \forall x_1, x_2 \in \mathbb{R}^n$.

A process $U$ on $\mathbb{R}^n$ is called almost periodic if for any sequence $\{s_n\} \subseteq \mathbb{R}$, there exists a subsequence $\{s_{n_k}\} \subseteq \{s_n\}$ such that the sequence $\{U_{s_n}(t, \tau)x\}$ converges to some $V(t, \tau)x$ in $\mathbb{R}^n$ uniformly in $t \in \mathbb{R}$ and pointwise in $(\tau, x) \in \mathbb{R}^+ \times \mathbb{R}^n$, where $U_s(t, \tau) := U(t + s, \tau)$ is the $s$-translation of $U(t, \tau)$, i.e., $U_s(t, \tau) := U(t + s, \tau)$.

A complete trajectory through $(t, x) \in \mathbb{R} \times \mathbb{R}^n$ is a map $u : \mathbb{R} \to \mathbb{R}^n$ such that $u(t) = x$ and $u(\tau + s) = U(s, \tau)u(s)$ for all $(s, \tau) \in \mathbb{R} \times \mathbb{R}^+$.

**Theorem 1.2.** (See [12]) Let $U = U(t, \tau)$ be an almost periodic linear contraction process on $\mathbb{R}^n$. Then, one of the following alternatives is fulfilled:

(i) There is a complete trajectory $z = z(s)$ of $U$ with constant positive norm;

(ii) There are two constants $C \geq 0$, $\delta > 0$ such that

$$\|U(t, \tau)\|_{[\mathbb{R}^n]} \leq Ce^{-\delta \tau},$$

for all $t \in \mathbb{R}$ and $\tau > 0$.

Denote by $\varphi(t, u_0, y)$ the unique solution of equation (1) with initial value $u_0$ at time $t = 0$. Then, from the general properties of linear equations, we have:

(C1) $\varphi(0, u, y) = u$ for all $u \in E$ and $y \in Y$;
(C2) $\varphi(t + \tau, u, y) = \varphi(t, \varphi(\tau, u, y), \sigma(\tau, y))$ for all $t, \tau \in \mathbb{R}$ and $(u, y) \in E \times Y$;
(C3) The mapping $\varphi : \mathbb{R} \times E \times Y \to E$ is continuous;
(C4) The mapping $\varphi(t, \cdot, y) : E \to E$ is linear for all $(t, y) \in \mathbb{R} \times Y$.

The triplet $(E, \varphi, (Y, \mathbb{R}, \sigma))$ (shortly $\varphi$) is said to be a cocycle [21] over the dynamical system $(Y, \mathbb{R}, \sigma)$, if the properties (C1)–(C3) are fulfilled. If, additionally, the property (C4) holds, then the cocycle $\varphi$ is called linear.

**Remark 3.** Below we will also consider more general cases. Namely,

(i) The one-sided cocycles, i.e., when the mapping $\varphi$ is defined only on $\mathbb{R}^+ \times E \times Y$;
(ii) The cocycles with discrete time, i.e., instead of the continuous time $\mathbb{R}$ (respectively, $\mathbb{R}^+$) we consider the discrete time $\mathbb{Z}$ (respectively, $\mathbb{Z}^+$).
The aim of this paper is to generalize the results of Cieutat and Haraux [12] (Theorem 1.1 and Theorem 1.2) previously stated to the case of general linear nonautonomous (cocycle) dynamical systems (Theorem 6.4 and Theorem 6.9), functional-differential equations (Theorem 6.15 and Theorem 6.16) and difference equations (Theorem 6.21 and Theorem 6.22).

The paper is organized as follows.

In Section 2, some notions and facts from the theory of nonautonomous dynamical systems are collected: cocycles, skew-product dynamical systems and nonautonomous dynamical systems; global attractors, etc.

Section 3 contains a brief summary of results from [9, 10] concerning bounded motions of linear nonautonomous dynamical systems with minimal base.

In Sections 4 and 5 we establish the main abstract results of our paper. Section 4 is dedicated to the study of linear contractive systems. The main result of this section is

**Theorem 4.5** Suppose that the following conditions are satisfied:

(i) The dynamical system \((Y, S, \sigma)\) is compact and minimal.
(ii) The linear nonautonomous dynamical system \((X, S_+, \pi), (Y, S, \sigma), h)\) is generated by the cocycle \(\phi\) (i.e. \(X = E \times Y, \pi = (\phi, \sigma)\) and \(h = pr_2 : X \to Y\)).
(iii) The dynamical system \((X, S_+, \pi)\) is asymptotically compact.
(iv) The cocycle \(\phi\) is nonexpanding, i.e., \(|\phi(t, u, y)| \leq |u|\) for all \((u, y) \in E \times Y\) and \(t \in S_+\).

Then, there are two vectorial positively invariant sub-fiberings \((X^0, h, Y)\) and \((X^s, h, Y)\) of \((X, h, Y)\) such that:

a. \(X_y = X^0_y + X^s_y\) and \(X^0_y \cap X^s_y = \{0\}\) for all \(y \in Y\), where \(\{0\} = (0, y) \in X = E \times Y\) and \(0\) is the zero in the Banach space \(E\).

b. The vector sub-fiber \((X^0, h, Y)\) is finite dimensional, invariant (i.e., \(\pi^t X^0 = X^0\) for all \(t \in S_+\)).

(i) For every \(x := (u, y) \in X^0_y\) there exists a unique entire trajectory of the dynamical system \((X, S_+, \pi)\) belonging to \(X^0\).

(ii) Every trajectory of the dynamical system \((X, S_+, \pi)\) belonging to \(X^0\) is recurrent, and its norm is constant, i.e. \(|\phi(t, u, y)| = |u|\) for all \(x = (u, y) \in X^s_y\) and \(t \in S\).

c. There exists two positive numbers \(N\) and \(\nu\) such that \(|\phi(t, u, y)| \leq N e^{-\nu t}|u|\) for all \((u, y) \in X^s\) and \(t \in S_+\).

Theorem 4.5 provides a detailed description of the asymptotic behavior of trajectories for the nonautonomous linear contractive systems with minimal base.

In Section 5, we investigate the existence of uniformly compatible (in the sense of Shcherbakov [23]-[26]) motions of linear non-homogeneous (affine) systems, if the corresponding linear homogeneous system is contractive (Theorem 5.3).

Finally, Section 6 is concerned with the applications of our general results, obtained in Section 4 and 5 to ordinary linear almost periodic (respectively, almost automorphic, recurrent) equations, functional-differential equations and difference equations. For example, the following results hold.

**Theorem 6.4** Suppose that the following conditions are satisfied:

(i) The dynamical system \((Y, \mathbb{R}, \sigma)\) is compact and minimal.

(ii) The operator-function \(A \in C(Y, [E])\) is dissipative.

(iii) The linear cocycle \(\varphi\), generated by equation (15), is asymptotically compact.
Then, one of the following alternatives is fulfilled:

a. For every $y \in Y$, equation (15) admits at least one recurrent solution with constant positive norm.

b. The trivial solution of equation (15) is uniformly exponentially stable, i.e., there exist two positive numbers $N$ and $\nu$ such that $|\varphi(t,u,y)| \leq Ne^{-\nu t}|u|$ for all $(u,y) \in X$ and $t \in \mathbb{R}_+$.

**Theorem 6.5** Assume the following hypotheses:

(i) The dynamical system $(Y, \mathbb{R}, \sigma)$ is compact and minimal.

(ii) The operator-function $A \in C(Y, [E])$ is dissipative.

(iii) The linear cocycle $\varphi$, generated by equation (15), is asymptotically compact.

Then, one of the following alternatives is fulfilled:

a. For every $y \in Y$, equation (15) admits at least one recurrent solution with constant positive norm.

b. For every $f \in C(Y, E)$, there exists a unique function $\nu_f \in C(Y, E)$ such that

$$
\phi_f(t, \nu_f(y), y) = \nu_f(\sigma(t, y))
$$

for all $t \in \mathbb{R}$ and $y \in Y$, where $\phi_f(t, u, y)$ is a unique solution of the equation

$$
v' = A(\sigma(t,y))v + f(\sigma(t,y)) \quad (y \in Y)
$$

passing through the point $u \in E$ at the initial moment $t = 0$.

**Remark 4.** Under the conditions of Theorem 6.5 if the statement b. holds and the point $y \in Y$ is quasi-periodic (respectively, almost periodic, almost automorphic, recurrent), then the solution $\varphi(t, \nu(y), y) = \nu(\sigma(t, y))$ of equation (16) is quasi-periodic (respectively, almost periodic, almost automorphic, recurrent).

Analogical results take place also for functional-differential equations and difference equations.

**2. Non-autonomous dynamical systems and global attractors.** To make this paper as much self-contained as possible, let us collect in this section some well-known concepts and results from the theory of dynamical systems which will be necessary for our analysis.

**2.1. Cocycles, skew-product dynamical systems and non-autonomous dynamical systems.** Let $\mathcal{T}_i$ ($i = 1, 2$) be a sub-semigroup of the group $\mathbb{S}$, and $\mathbb{S}_+ \subseteq \mathcal{T}_1 \subseteq \mathcal{T}_2 \subseteq \mathbb{S}$. Consider now two dynamical systems $(X, \mathcal{T}_1, \pi)$ and $(Y, \mathcal{T}_2, \sigma)$. A triplet $\langle X, \mathcal{T}_1, \pi \rangle$, $\langle (Y, \mathcal{T}_2, \sigma), h \rangle$ is called a nonautonomous dynamical system if $h$ is a homomorphism from $(X, \mathcal{T}_1, \pi)$ onto $(Y, \mathcal{T}_2, \sigma)$.

Let $\langle (Y, \mathcal{T}_2, \sigma), h \rangle$ be a dynamical system on $Y$, $W$ a complete metric space, and $\varphi$ a continuous mapping from $\mathcal{T}_1 \times W \times Y$ in $W$, possessing the following properties:

a. $\varphi(0, u, y) = u$ ($u \in W, y \in Y$);

b. $\varphi(t + \tau, u, y) = \varphi(\tau, \varphi(t, u, y), \sigma(t, y))$ ($t, \tau \in \mathcal{T}_1, u \in W, y \in Y$).

Then, the triplet $\langle W, \varphi, (Y, \mathcal{T}_2, \sigma) \rangle$ (or shortly $\varphi$) is called a cocycle on $(Y, \mathcal{T}_2, \sigma)$ with fiber $W$ (see [21]).

Given a cocycle $\langle W, \varphi, (Y, \mathcal{T}_2, \sigma) \rangle$, let us set $X := W \times Y$, and define a mapping $\pi : \mathcal{T}_1 \times X \rightarrow X$ as follows: $\pi(t, (u, y)) := (\varphi(t, u, y), \sigma(t, y))$ (i.e., $\pi = (\varphi, \sigma)$).

Then, it is easy to see that $\langle X, \mathcal{T}_1, \pi \rangle$ is a dynamical system on $X$, which is called a skew-product dynamical system [21] and $h = pr_2 : X \rightarrow Y$ is a homomorphism from
Thus, if we have a cocycle \( (W, \varphi, (Y, \mathbb{T}_2, \sigma)) \) on the dynamical system \((Y, \mathbb{T}_2, \sigma)\) with fiber \(W\), then it generates a nonautonomous dynamical system \((X, \mathbb{T}_1, \pi)\), \((Y, \mathbb{T}_2, \sigma), h\) \((X := W \times Y)\), called the nonautonomous dynamical system generated by the cocycle \((W, \varphi, (Y, \mathbb{T}_2, \sigma))\) on \((Y, \mathbb{T}_2, \sigma)\).

Below we will give an example of nonautonomous dynamical system which is not generated by a cocycle.

**Example 2.1.** (NDS generated by tangent flow.) Let \(M\) be a compact differentiable manifold and \((M, \mathcal{R}, \sigma)\) be a differentiable flow on \(M\). Denote by \(TM\) the tangent bundle of \(M\) and by \(D\sigma : \mathcal{R} \times TM \to TM\) the derivative flow on \(TM\): if \(x := (u, y) \in TM\), i.e., \(u \in T_y M\) \((T_y M\) is the tangent space for \(M\) at the point \(y \in M\)), then \(\pi(t, (u, y)) := (D\sigma^t(y)u, \sigma^t(y))\) where \(\sigma^t(y) := \sigma(t, y)\) for all \(t \in \mathbb{R}\) and \(y \in Y\). The triplet \((TM, \mathcal{R}, \pi), (M, \mathcal{R}, \sigma), h\) where \(h : TM \to M\) is the natural projection \((h(u, y) := y\) for all \(y \in Y\) and \(u \in T_y M\), is a (linear) nonautonomous dynamical system.

It is well known that nonautonomous dynamical systems (cocycles) play a very important role in the study of nonautonomous evolutionary differential equations. Under appropriate assumptions, every nonautonomous differential equation generates a cocycle (a nonautonomous dynamical system).

### 2.2. Global attractors of dynamical systems.

Let \(M \subseteq X\). The set

\[
\omega(M) := \bigcap_{t \geq 0} \bigcup_{\tau \geq t} \pi(\tau, M)
\]

is called the \(\omega\)-limit set of \(M\).

The set \(M\) is called **orbitally stable**, if for every \(\varepsilon > 0\) there exists \(\delta = \delta(\varepsilon) > 0\) such that \(\rho(x, M) < \delta\) implies \(\rho(\pi(t, x), M) < \varepsilon\) for all \(t \geq 0\).

The dynamical system \((X, T, \pi)\) is called:

- **point dissipative** if there exists a nonempty compact subset \(K \subseteq X\) such that for every \(x \in X\)

\[
\lim_{t \to +\infty} \rho(\pi(t, x), K) = 0;
\]

- **compact dissipative** if the equality (4) takes place uniformly with respect to \(x\) on every compact subset of \(X\);

- **locally complete** (compact) if for any point \(p \in X\), there exist \(\delta_p > 0\) and \(l_p > 0\) such that the set \(\pi(l_p, B(p, \delta_p))\) is relatively compact, where \(B(x, \delta) := \{x \in X \mid \rho(x, p) < \delta\}\).

Let \((X, T, \pi)\) be compact dissipative and \(K\) be a compact set attracting every compact subset of \(X\). Let us set

\[
J_X := \omega(K) := \bigcap_{t \geq 0} \bigcup_{\tau \geq t} \pi(\tau, K).
\]

It can be shown [10, Ch.I] that the set \(J_X\) defined by equality (5) does not depend on the choice of the attractor \(K\), but is characterized only by the properties of the dynamical system \((X, T, \pi)\) itself. The set \(J_X\) is called a Levinson center of the compact dissipative dynamical system \((X, T, \pi)\).

The next theorem characterizes the compact dissipative dynamical systems.
Theorem 2.2. (See [10, ChI]) Let \((X, \mathbb{T}, \pi)\) be point dissipative. For \((X, \mathbb{T}, \pi)\) to be compact dissipative it is necessary and sufficient that there exists a nonempty compact set \(M\) possessing the following properties:

(i) \(\Omega_X := \bigcup \{ \omega(x) : x \in X \} \subseteq M\);

(ii) \(M\) is orbitally stable.

In this case, \(J_X \subseteq M\) where \(J_X\) is the center of Levinson of \((X, \mathbb{T}, \pi)\).

Recall that a dynamical system \((X, \mathbb{S}, \pi)\) is said to be asymptotically compact if for any bounded positively invariant set \(B \subseteq X\), there is a nonempty compact dissipative set \(K \subseteq X\) such that

\[
\lim_{t \to +\infty} \sup \{ \rho(\pi(t, x), K) \mid x \in B \} = 0.
\]

A continuous mapping \(\gamma : \mathbb{S} \to X\) is said to be an entire (full) trajectory of the dynamical system \((X, \mathbb{T}, \pi)\), if \(\gamma(t + \tau) = \pi(t, \gamma(\tau))\) for all \(t \in \mathbb{T}\) and \(\tau \in \mathbb{S}\).

Denote by \(\Phi_x\) the set of all entire trajectories of \((X, \mathbb{T}, \pi)\) with \(\gamma(0) = x\) and \(\Phi := \bigcup \{ \Phi_x : x \in X \}\).

Remark 5. (i) Assume that \(x \in X\) is such that \(\Sigma_x^+ := \{ \pi(t, x) \mid t \in \mathbb{S}_+ \}\) is bounded, and \((X, \mathbb{T}, \pi)\) is asymptotically compact. Then, \(\Sigma_x^+\) is relatively compact.

(ii) Let \(M \subseteq X\) be bounded and invariant. Then, \(M\) is relatively compact if the dynamical system \((X, \mathbb{T}, \pi)\) is asymptotically compact. In particular, if \(x \in X\) and \(\gamma \in \Phi_x\) is such that \(\gamma(\mathbb{S})\) is bounded, then \(\gamma(\mathbb{S})\) is relatively compact.

3. Bounded motions of linear systems. Let \((X, h, Y)\) be a locally trivial Banach fiber bundle (see [4]), and recall that a nonautonomous dynamical system \(\langle (X, \mathbb{T}, \pi), (Y, \mathbb{S}, \sigma), h \rangle\) is said to be linear (see [6], [19, 20]) if the map \(\pi(t, \cdot) : X_y \to X_{\sigma(t,y)}\) is linear for every \(t \in \mathbb{T}\) and \(y \in Y\).

The nonautonomous dynamical system \(\langle (X, \mathbb{T}, \pi), (Y, \mathbb{S}, \sigma), h \rangle\) is said to be distal on \(\mathbb{S}_+\) in the fiber \(X_y := \{ x \in X \mid h(x) = y \}\) if \(\inf \{ \rho(\pi(t, x_1), \pi(t, x_2)) \mid t \in \mathbb{S}_+ \} > 0\) for all \(x_1, x_2 \in X_y, x_1 \neq x_2\) (see [5, 16]).

In the case of a group nonautonomous dynamical system, the concept of distalness on \(\mathbb{S}_+\) and \(\mathbb{S}_-\) on the fiber \(X_y\) can be defined likewise.

A nonautonomous system is said to be distal on \(\mathbb{S}_+\) (\(\mathbb{S}_-\), \(\mathbb{S}\)), if it is distal in every fiber \(X_y, y \in Y\).

The following lemma provides more information on distal nonautonomous dynamical systems.

Lemma 3.1. (See [5, 16]) The following assertions hold.

(i) Assume that \(X\) is compact, and \((Y, \mathbb{S}, \sigma)\) is minimal. If the group nonautonomous dynamical system \(\langle (X, \mathbb{S}, \pi), (Y, \mathbb{S}, \sigma), h \rangle\) is distal on \(\mathbb{S}_+ (\mathbb{S}_-)\), then it is distal on \(\mathbb{S}\).

(ii) Assume that \(X\) is compact, \((Y, \mathbb{S}, \sigma)\) is minimal, and \(y \in Y\). Then, the following conditions are equivalent:

(a) The group nonautonomous system \(\langle (X, \mathbb{S}, \pi), (Y, \mathbb{S}, \sigma), h \rangle\) is distal on \(\mathbb{S}\) in the fiber \(X_y\);

(b) For any points \(x_1, \ldots, x_k \in X\), where \(k \geq 2\) is an integer, the point \((x_1, \ldots, x_k) \in X^k\) is recurrent in \((X^k, \mathbb{S}, \pi)\).

Assume that \((X_i, \mathbb{T}, \pi_i)\) is a dynamical system on \(X_i, i = 1, \ldots, k\); let \(X := X_1 \times \ldots \times X_k\), and let \(\pi := (\pi_1, \ldots, \pi_k) : X \times \mathbb{T} \to X\) be defined by the formula

\[
\pi(x, t) := (\pi_1(x_1, t), \ldots, \pi_k(x_k, t)).
\]
for all \( t \in T \) and \( x := (x_1, \ldots, x_k) \in X \).

The dynamical system \((X, T, \pi)\), where \( X := X_1 \times \cdots \times X_k \) and \( \pi := (\pi_1, \ldots, \pi_k) \), is called the direct product of the dynamical systems \((X_i, T, \pi_i), i = 1, \ldots, k\) and denoted by \((X_1, T, \pi_1) \times \cdots \times (X_k, T, \pi_k)\).

If \( X_i = X, i = 1, \ldots, k \), and \( \pi_i = \pi, i = 1, \ldots, k \), then
\[
(X, T, \pi) \times (X, T, \pi) \times \cdots \times (X, T, \pi) := (X^k, T, \pi).
\]

The direct product of group dynamical systems is defined likewise.

The points \( x_1, \ldots, x_k \in X \) are said to be jointly recurrent if the point \((x_1, \ldots, x_k) \in X^k\) is recurrent in the dynamical system \((X^k, T, \pi)\).

If \((\langle X, T, \pi \rangle, (Y, S, \sigma), h)\) is a skew product over \((Y, S, \sigma)\) with the fiber \( E \), then it is linear if and only if \( E \) is a Banach space and the map \( \varphi(t, \cdot, y) : E \to E \) is linear for every \( y \in Y \) and \( t \in T \).

Throughout the rest of this section we assume that \( Y \) is compact, the dynamical system \((Y, S, \sigma)\) is minimal, \( X = E \times Y, E \) is a Banach space with norm \(| \cdot |\), the nonautonomous dynamical system \((\langle X, T, \pi \rangle, (Y, S, \sigma), h)\) is linear, \( \pi = (\varphi, \sigma) \), and \( h = pr_2 \).

Let \( F \subseteq E \times Y \) be a closed vectorial subset of the trivial fiber bundle \((E \times Y, pr_2, Y)\) that is positively invariant relative to \((X, T, \pi)\). We set
\[
\mathbb{B}^+ := \{(x, y) \in F \mid \sup\{|\varphi(t, x, y)| : t \in S_+\} < +\infty\}.
\]

The set \( \mathbb{B}^- \) is defined likewise. If \( (\langle X, S_+, \pi \rangle, (Y, S, \sigma), h) \) is a semigroup nonautonomous dynamical system, then \( \mathbb{B} \) is the set of all points of \( F \) with the following property: there is an entire trajectory of the dynamical system \((F, S_+, \pi)\) which is bounded on \( S \), and which passes through this point. We put \( \mathbb{B}^+_y := \mathbb{B}^+ \cap X_y \) and \( \mathbb{B}_y := \mathbb{B} \cap X_y, y \in Y \).

We can now establish the following result.

**Theorem 3.2.** (See [9, 10]) Assume that \((\langle X, S_+, \pi \rangle, (Y, S, \sigma), h)\) is a linear nonautonomous dynamical system, \((X, S_+, \pi)\) is asymptotically compact, and there is an \( M > 0 \) such that the inequality
\[
|\varphi(t, x, y)| \leq M|x|
\]
is fulfilled for all \( \gamma \in \Phi_{(x, y)}, (x, y) \in \mathbb{B}, \) and \( t \in S \). Then, the following assertions hold:

(i) Any two different entire trajectories \( \gamma_1 \) and \( \gamma_2 \) \((h(\gamma_1(0)) = h(\gamma_2(0)))\) are jointly recurrent;

(ii) For any \((x, y) \in \mathbb{B}\), the set \( \Phi_{(x, y)} \) consists of a single entire recurrent trajectory;

(iii) \( \mathbb{B} \) is closed in \( F \);

(iv) \((X, S_+, \pi)\) induces a group dynamical system \((\mathbb{B}, S, \pi)\) on \( \mathbb{B} \);

(v) For any \( y \in Y \), the set \( \mathbb{B}_y \) is finite-dimensional and \( \dim \mathbb{B}_y \) does not depend on \( y \in Y \).

We conclude this section with a sufficient condition ensuring that a linear nonautonomous system is asymptotically compact.

Let \( P : X \to X \) be a projection of the vector bundle, that is, \( P_y := P|_{X_y} \) projection in \( X_y \) for every \( y \in Y \). Then, \( P \) is said to be completely continuous if \( P(M) \) is relatively compact for any bounded set \( M \subseteq X \).

Recall that a dynamical system \((X, S_+, \pi)\) is said to be conditionally \( \beta \)-condensing (see [15]) if there exists \( t_0 > 0 \) such that \( \beta(\pi(t_0, B)) < \beta(B) \) for all bounded sets \( B \).
in $X$ with $\beta(B) > 0$. The dynamical system $(X, S_+, \pi)$ is said to be $\beta$-condensing if it is conditionally $\beta$-condensing and the set $\pi(t_0, B)$ is bounded for all bounded sets $B \subseteq X$.

According to Lemma 2.3.5 in [15, p.15] and Lemma 3.3 in [8], a conditionally condensing dynamical system $(X, S_+, \pi)$ is asymptotically compact.

A cocycle $(E, \varphi, (Y, T, \sigma))$ is called conditionally $\alpha$-condensing if there exists $t_0 > 0$ such that, for any bounded set $B \subseteq E$, the inequality $\alpha(\varphi(t_0, B, Y)) < \alpha(B)$ holds if $\alpha(B) > 0$. The cocycle $\varphi$ is called $\alpha$-condensing if it is a conditionally $\alpha$-condensing cocycle, and the set $\varphi(t_0, B, Y) = \cup\{\varphi(t_0, u, Y) | u \in B, y \in Y\}$ is bounded for all bounded set $B \subseteq E$.

A cocycle $\varphi$ is said to be a conditionally $\alpha$-contraction of order $k \in [0, 1)$, if there exists $t_0 > 0$ such that for any bounded set $B \subseteq E$ for which $\varphi(t_0, B, Y) = \cup\{\varphi(t_0, u, Y) | u \in B, y \in Y\}$ is bounded, the inequality $\alpha(\varphi(t_0, B, Y)) \leq k\alpha(B)$ holds. The cocycle $\varphi$ is called $\alpha$-contraction if it is a conditionally $\alpha$-contraction cocycle, and the set $\varphi(t_0, B, Y) = \cup\{\varphi(t_0, u, Y) | u \in B, y \in Y\}$ is bounded for all bounded sets $B \subseteq E$.

Let us now recall a helpful result to determine when a cocycle is an $\alpha$-contraction.

**Theorem 3.3.** (See [9, 10]) Let $E$ be a Banach space, and $\varphi$ a cocycle on $(Y, S, \sigma)$ with fiber $E$, which satisfies the following conditions:

(i) $\varphi(t, u, y) = \psi(t, u, y) + \gamma(t, u, y)$ for all $t \in S_+, u \in E$ and $y \in Y$.

(ii) There exists a function $m: \mathbb{R}^+_0 \rightarrow \mathbb{R}_+$ satisfying the condition $m(t, r) \to 0$ as $t \to +\infty$ (for every $r > 0$) such that $|\psi(t, u_1, y) - \psi(t, u_2, y)| \leq m(t, r)|u_1 - u_2|$ for all $t \in S_+, u_1, u_2 \in B[0, r]$ and $y \in Y$.

(iii) $\gamma(t, A, Y)$ is compact for all bounded $A \subseteq X$ and $t > 0$.

Then, the cocycle $\varphi$ is an $\alpha$-contraction.

**Lemma 3.4.** (See [10, ChXIII]) Let $Y$ be compact and the cocycle $\varphi$ be $\alpha$-condensing. Then, the skew-product dynamical system $(X, T, \pi)$ is also $\alpha$-condensing.

4. **Linear contractive systems.** We will analyze in this section the asymptotic properties of linear contractive nonautonomous dynamical systems.

Let $X$ be a Banach space, let $C(S, X)$ be the space of all continuous maps $\varphi: S \rightarrow X$ equipped with the compact-open topology, and let $(C(S, X), S, \sigma)$ be the dynamical system of translations (shifts) on $C(S, X)$. Let $d$ be a metric on $C(S, X)$, which is consistent with its topology (for example, the Bebutov metric).

A linear nonautonomous dynamical system $\langle (X, S_+, \pi), (Y, S, \sigma), h \rangle$ is said to be contractive, if

$$|\pi(t, x)| \leq |x|,$$

for all $t \in S_+$ and $x \in X$.

A subset $M \subseteq Y$ is said to be minimal if $H(y) = M$ for all $y \in M$, where $H(y) := \{\sigma(t, y) : t \in S\}$.

We can now prove the following result.

**Lemma 4.1.** Suppose that the following conditions hold:

(i) $\langle (X, S_+, \pi), (Y, S, \sigma), h \rangle$ is a linear nonautonomous contractive dynamical system;

(ii) $\gamma: S \rightarrow X$ is an entire relatively compact trajectory (i.e. the set $\gamma(S)$ is compact).

(iii) The dynamical system $(Y, S, \sigma)$ is compact and minimal.
Then, the following statements take place:
\[(i) \quad |\gamma(t)| \geq |\gamma(0)| \quad (7)\]
for all \(t \in \mathbb{S}_-\);

\[(ii) \quad \text{The full trajectory } \gamma \text{ is recurrent, i.e., the function } \gamma : \mathbb{S} \to X \text{ is recurrent w.r.t. the shift dynamical system (the Bebutov dynamical system) } (C(\mathbb{S}, X), \mathbb{S}, \sigma); \]

\[(iii) \quad |\gamma(t)| = |\gamma(0)| \text{ for all } t \in \mathbb{S}. \]

Proof. Let \(\gamma\) be an entire trajectory of \((X, \mathbb{S}_+, \pi)\). Then,
\[\gamma(t + \tau) = \pi(t, \gamma(\tau)) \quad (8)\]
for all \(t \in \mathbb{S}_+\) and \(t \in \mathbb{S}\). From (6) and (8) we obtain (7).

To prove the second statement we consider the nonautonomous dynamical system \(\langle (H(\gamma), \mathbb{S}, \sigma), (Y, \mathbb{S}, \lambda), \tilde{H} \rangle\), where \(H(\gamma) := \{\sigma(\tau, \gamma) : \tau \in \mathbb{S}\}\) and \(\sigma(\tau, \gamma)(t) := \gamma(\tau + t)\) for all \(\tau, t \in \mathbb{S}\), noting that by bar it is denoted the closure in the space \(C(\mathbb{S}, X)\), \((H(\gamma), \mathbb{S}, \sigma)\) is the shift dynamical system on \(H(\gamma)\) induced by the Bebutov dynamical system \((C(\mathbb{S}, X), \mathbb{S}, \sigma)\), and \(\tilde{H}\) is the mapping from \(H(\gamma)\) onto \(Y\) defined by the equality \(\tilde{H}(\psi) := h(\psi(0))\) for all \(\psi \in H(\gamma)\). Since \(\gamma\) is relatively compact, then the set \(H(\gamma)\) is compact in the space \(C(\mathbb{S}, X)\). From the inequality (7) it follows that the nonautonomous dynamical system \(\langle (H(\gamma), \mathbb{S}, \sigma), (Y, \mathbb{S}, \lambda), \tilde{H} \rangle\) is distal in the negative direction. Since the system \((Y, \mathbb{S}, \lambda)\) is minimal, then by Lemma 3.1 it is also distal in the positive direction, and the function \(\gamma \in C(\mathbb{S}, X)\) is recurrent.

Now, we will prove the third statement of Lemma. Denote by \(\varphi(t) := |\gamma(t)|\). It is evident that \(\varphi \in C(\mathbb{S}, \mathbb{R})\) is a recurrent function and \(\varphi(t_2) = |\varphi(t_2 - t_1, \gamma(t_1))| \leq |\gamma(t_1)| = \varphi(t_1)\) for all \(t_2 \geq t_1 (t_1, t_2 \in \mathbb{S})\), i.e. the function \(\varphi\) is nonincreasing. From the last property of the function \(\varphi\) and its recurrence, it follows that \(\varphi\) is a constant. In fact, if we assume that there exists a \(t_0 \in \mathbb{S}\) such that \(\varphi(t_0) \neq \varphi(0)\), then, without loss of generality, we may suppose that \(\varphi(t_0) < \varphi(0)\). Since the function is recurrent, then there exists a sequence \(\{t_n\} \subset \mathbb{S}\) such that \(t_n \to +\infty\) and \(\gamma(t + t_n) \to \gamma(t)\) uniformly w.r.t. \(t\) on every compact from \(\mathbb{S}\). In particular we have \(\varphi(t_n) \leq \varphi(t_0) < \varphi(0)\) for sufficiently large \(n\). Thus we will have \(\varphi(0) = \lim_{n \to +\infty} \varphi(t_n) \leq \varphi(t_0) < \varphi(0)\). This contradiction proves our statement. \(\square\)

Remark 6. Notice that the first statement holds without assuming any compactness and minimality of \((Y, \mathbb{S}, \lambda)\).

Theorem 4.2. Let \(\langle (X, \mathbb{T}_1, \pi), (Y, \mathbb{T}_2, \sigma), h \rangle\) be a nonautonomous dynamical system, and \(M \neq \emptyset\) be a compact positively invariant set. Suppose that the following conditions are fulfilled:

\[(i) \quad h(M) = Y; \]

\[(ii) \quad M_y := M \cap X_y \text{ contains a single point } (i.e., M_y = \{m_y\} \text{ for all } y \in Y; \]

\[(iii) \quad M \text{ is uniformly stable, i.e., for all } \varepsilon > 0 \text{ there is a } \delta = \delta(\varepsilon) > 0 \text{ such that } \rho(x, m_y) < \delta (x \in X_y) \text{ implies } \rho(\pi(t, x), m_{\sigma(t,y)}) < \varepsilon \text{ for all } t \geq 0. \]

Then, \(M\) is orbitally stable.

Proof. We will show that set \(M\) is orbitally stable in \((X, \mathbb{T}_1, \pi)\). Suppose that it is not true, then there exist \(\varepsilon_0 > 0, \delta_n \to 0, x_n \in B(M, \delta_n) := \cup\{B(x, \delta_n) : x \in M\}\) and \(t_n \to +\infty\) such that
\[\rho(\pi(t_n, x_n), M) \geq \varepsilon_0. \quad (9)\]
Since $M$ is compact, then we may suppose that the sequence $\{x_n\}$ is convergent. Let $x_0 := \lim_{n \to +\infty} x_n$, with $x_{y_n} \in M_{y_n}$, $\rho(x_n, M) = \rho(x_n, x_{y_n})$ and $y_0 = h(x_0)$. Then, $x_0 = \lim_{n \to +\infty} x_{y_n}$ and $x_0 \in M_{y_0}$.

Let $q_n = h(x_n)$ and note that

$$\rho(x_n, x_{q_n}) \leq \rho(x_n, x_{y_n}) + \rho(x_{y_n}, x_{q_n}) \to 0$$  \hspace{1cm} (10)

as $n \to +\infty$, because $q_n \to y_0$ and $x_{q_n} \to x_0$. Taking into account (10) and the asymptotic stability of the set $M$, we have

$$\rho(\pi(t_n, x_n), \pi(t_n, x_{q_n})) \to 0. \hspace{1cm} (11)$$

But the equalities (9) and (11) are contradictory. Hence, the set $M$ is orbitally stable in $(X, T_1, \pi)$.

\begin{theorem}
Suppose that $((X, S^+), (Y, S, \sigma), h)$ is a linear nonautonomous dynamical system satisfying the following conditions:

(i) $Y$ is compact;

(ii) The dynamical system $(X, S^+, \pi)$ is asymptotically compact;

(iii) There exists a positive number $M$ such that $|\pi(t, x)| \leq M|x|$ for all $t \in S^+$ and $x \in X$.

Then, the following assertions are equivalent:

(i) The nonautonomous dynamical system $((X, S^+), (Y, S, \sigma), h)$ is point dissipative and $B \subseteq \Theta$, where $\Theta$ is the zero section of the vector fibering $(X, h, Y)$ defined by $\Theta := \{y \in Y, \theta_y \in X_y, |\theta_y| = 0\}$;

(ii) There exist positive number $N, \nu$ such that $|\pi(t, x)| \leq Ne^{-\nu t}|x|$ for all $t \in S^+$ and $x \in X$.

\end{theorem}

\begin{proof}
Denote by $\Theta = \{\theta_y : y \in Y, \theta_y \in X_y, |\theta_y| = 0\}$ the zero section of the vector fibering $(X, h, Y)$. Since $(X, h, Y)$ is locally trivial and $Y$ is compact, then $\Theta$ is a compact positively invariant set of the dynamical system $(X, S^+, \pi)$, $\Theta \cap X_y$ contains a single point $\theta_y$, and $\Theta$ is uniformly stable, i.e., for every $\varepsilon > 0$ there exists a positive number $\delta = \delta(\varepsilon)$ such that $|x| < \delta$ implies $|\pi(t, x)| < \varepsilon$ for all $t \in S^+$ and $x \in X$. By Theorem 4.2 the set $\Theta$ is orbitally stable. Since $(X, S^+, \pi)$ is point dissipative, then $\Omega_X \subseteq \Theta$, where $\Omega_X := \bigcup \{x \in X, x \in \Phi^0 \}$. According to Theorem 2.2 the dynamical system $(X, S^+, \pi)$ is compact dissipative.

Assume now that the nonautonomous dynamical system $((X, S^+, \pi), (Y, S, \sigma), h)$ is uniformly exponentially stable. Then, according to Theorem 2.11.3 in [10, Ch.II], it is locally dissipative. Let $J_X$ be its Levinson centre (i.e., the maximal compact invariant set of the dynamical system $(X, S^+, \pi)$). We note that, according to the linearity of the nonautonomous dynamical system $((X, S^+, \pi), (Y, S, \sigma), h)$, we have $J_X = \hat{\Theta} := \Theta \cap h^{-1}(J_Y)$. Let $\varphi$ be an entire bounded trajectory of the dynamical system $(X, S^+, \pi)$. Since the nonautonomous dynamical system $((X, S^+, \pi), (Y, S, \sigma), h)$ is asymptotically compact, and the set $M = \varphi(S)$ is relatively compact, we note that $\varphi(S) \subseteq J_X = \hat{\Theta}$ because $J_X$ is the maximal compact invariant set of $(X, S^+, \pi)$. The theorem is therefore proved.

\end{proof}

\begin{theorem}
Suppose that the following conditions are satisfied:

(i) The dynamical system $(Y, S, \sigma)$ is compact and minimal.

\end{theorem}
Theorem 4.5. The linear nonautonomous dynamical system \((X,S_+,\pi),(Y,S,\sigma),h)\) is generated by the cocycle \(\varphi\) (i.e., \(X = E \times Y, \pi = (\varphi, \sigma)\) and \(h = pr_2: X \to Y\)).

Proof. Let \(X_{\varphi} = X^0 + X^\sigma\) and \(X^0 \cap X^\sigma = \emptyset\) for all \(y \in Y\), where \(\emptyset = (0, y) \in X = E \times Y\) and \(0\) is the zero in the Banach space \(E\).

Theorem 4.4, the dynamical system \((X, S_+, \pi)\) is asymptotically compact.

There exists a positive number \(\mu\) such that \(|\varphi(t, u, y)| \leq \mu|u|\) for all \(t \in Y\) and \(y \in S_+\).

Then, there are two vectorial positively invariant sub-fiberings \((X^0, h, Y)\) and \((X^\sigma, h, Y)\) of \((X, h, Y)\) such that:

a. \(X_y = X^0 + X^\sigma\) and \(X^0 \cap X^\sigma = 0\) for all \(y \in Y\), where \(\emptyset = (0, y) \in X = E \times Y\) and \(0\) is the zero in the Banach space \(E\).

b. \(\varphi(t, u, y)\) is nonexpanding, i.e., \(|\varphi(t, u, y)| \leq |u|\) for all \((u, y) \in X^0\) and \(t \in S_+\).

The dynamical system \((X, S_+, \pi)\) is asymptotically compact.

Proof. Let \(X^0 := \mathbb{B}\). Then, according to Theorem 3.2, statement b. holds. Denote by \(P_y\) the projection of \(X_y := h^{-1}(y)\) to \(\mathbb{B}_y := \mathbb{B} \cap h^{-1}(y)\), then \(P_y(u, y) = (\mathcal{P}(u, y), y)\) for all \(u \in E, \mathcal{P}(y) = \mathcal{P}(y)\) and the mapping \(\mathcal{P}: Y \to [E] (y \to \mathcal{P}(y))\) is continuous, where we recall that \([E]\) denotes the set of all linear continuous operators acting on \(E\). Now we set \(X^0 = \mathcal{Q}(y)X^0\) and \(X^\sigma = \mathcal{Q}(y)X^\sigma\), where \(\mathcal{Q}(y) := 1_{\mathbb{B}}\).

We will show that \(X^\sigma\) is closed in \(X\). In fact, let \(\{x_n\} \subseteq X^\sigma\) and \(x_0 = \lim_{n \to \infty} x_n\). Note that \(P_{y_0}(x_0) = (\mathcal{P}(y_0)u_0, y_0) = \theta_{y_0}\) and, consequently, \(x_0 \in X^0_{y_0} \subseteq X^0\).

Let \((X^\sigma, S^\sigma, \pi)\) be the dynamical system induced by \((X, S^+, \pi)\). It is clear that, under the conditions of Theorem 4.4, the dynamical system \((X^\sigma, S^+, \pi)\) is asymptotically compact and every positive semi-trajectory is relatively compact and, consequently, \(\lim_{t \to \infty} \pi(t, x) = 0\) for all \(x \in X^\sigma\), because the dynamical system \((X^\sigma, S^+, \pi)\) does not possess any nontrivial entire trajectory bounded on \(S\). Indeed, if we suppose that it is not true, then there exist \(x_0 = (u_0, y_0)\) and \(t_n \to +\infty\) such that \(|u_0| \neq 0\) and \(\lim_{n \to \infty} \pi(t_n, x) = x_0\), and there exists a nontrivial entire trajectory, which is bounded on \(S\), passing through the point \(x_0\). This contradiction proves the necessary assertion. Thus, by applying Theorem 4.3, there exist two positive constants \(N\) and \(\nu\) such that \(|\varphi(t, u, y)| \leq Ne^{-\nu|u|}\) for all \((u, y) \in X^0\) and \(t \in S_+\). The theorem is proved.

Theorem 4.5. Suppose that the following conditions are satisfied:

(i) The dynamical system \((Y, S, \sigma)\) is compact and minimal.

(ii) The linear nonautonomous dynamical system \((X, S_+, \pi), (Y, S, \sigma), h)\) is generated by the cocycle \(\varphi\) (i.e., \(X = E \times Y, \pi = (\varphi, \sigma)\) and \(h = pr_2: X \to Y\)).

(iii) The dynamical system \((X, S_+, \pi)\) is asymptotically compact.

(iv) The cocycle \(\varphi\) is nonexpanding, i.e., \(|\varphi(t, u, y)| \leq |u|\) for all \((u, y) \in E \times Y\) and \(t \in S_+\).

Then, there are two vectorial positively invariant sub-fiberings \((X^0, h, Y)\) and \((X^\sigma, h, Y)\) of \((X, h, Y)\) such that:

a. \(X_y = X^0 + X^\sigma\) and \(X^0 \cap X^\sigma = \emptyset\) for all \(y \in Y\), where \(\emptyset = (0, y) \in X = E \times Y\) and \(0\) is the zero in the Banach space \(E\).

b. \(\varphi(t, u, y)\) is finite dimensional, invariant (i.e., \(\pi^t X^0 = X^0\) for all \(t \in S_+\)).
(i) For every \( x := (u, y) \in X_y^0 \) there exists a unique entire trajectory of the dynamical system \( (X, \mathcal{S}_+, \pi) \) belonging to \( X_y^0 \).

(ii) Every trajectory of the dynamical system \( (X, \mathcal{S}_+, \pi) \) belonging to \( X_y^0 \) is recurrent, and its norm is constant, i.e. \( |\varphi(t, u, y)| = |u| \) for all \( x = (u, y) \in X_y^0 \) and \( t \in \mathbb{S} \).

c. There exists two positive numbers \( N \) and \( \nu \) such that \( |\varphi(t, u, y)| \leq Ne^{-\nu t}|u| \) for all \( (u, y) \in X^s \) and \( t \in \mathbb{S}_+ \).

**Proof.** This theorem follows directly from Theorem 4.4 and Lemma 4.1. \( \square \)

**Corollary 4.6.** Suppose that the following conditions are satisfied:

(i) The dynamical system \((Y, \mathcal{S}, \sigma)\) is compact and minimal.

(ii) The linear nonautonomous dynamical system \((S, \mathcal{S}_+, \pi)\) is generated by the cocycle \( \varphi \).

(iii) The dynamical system \((X, \mathcal{S}_+, \pi)\) is asymptotically compact.

(iv) The cocycle \( \varphi \) is nonexpanding.

Then, one of the following alternatives is fulfilled:

a. There is an entire trajectory \( \gamma \) of \((X, \mathcal{S}_+, \pi)\) with constant positive norm.

b. There exist two positive numbers \( N \) and \( \nu \) such that \( |\varphi(t, u, y)| \leq Ne^{-\nu t}|u| \) for all \( (u, y) \in X \) and \( t \in \mathbb{S}_+ \).

**Remark 7.** Theorems 4.3–4.5 generalize some results from [9, 10], where these facts were proved for conditionally \( \alpha \)-condensing systems.

5. **Comparability and uniform comparability of motions by the character of recurrence in the sense of Shcherbakov.** Let \((Y, \mathbb{T}, \sigma)\) be a dynamical system. A point \( y \in Y \) is said to be positively (respectively, negatively) stable in the sense of Poisson (see, for example, [26] and [28]), if there exists a sequence \( t_n \to +\infty \) (respectively, \( t_n \to -\infty \)) such that \( \sigma(t_n, y) \to y \) if the point \( y \) is Poisson stable in both directions, it is called Poisson stable.

Denote by \( \mathfrak{N}_y = \{ t_n \subset \mathbb{T} \mid \sigma(t_n, y) \to y, \text{ as } n \to +\infty \} \).

A point \( x \in X \) is called comparable with \( y \in Y \) by the character of recurrence if \( \mathfrak{N}_y \subseteq \mathfrak{N}_x \) (see [23–26]).

**Remark 8.** If a point \( x \in X \) is comparable with \( y \in Y \) by the character of recurrence, and \( y \) is stationary (respectively, \( \tau \)-periodic, recurrent, Poisson stable), then so is the point \( x \) (see [26]).

Denote by \( \mathfrak{M}_y := \{ \{ t_n \} \subset \mathbb{T} \mid \text{the sequence } \{ \sigma(t_n, y) \} \text{ is convergent} \} \).

A point \( x \in X \) is called uniformly comparable with \( y \in Y \) by the character of recurrence if \( \mathfrak{M}_y \subseteq \mathfrak{M}_x \) (see [23–26]).

**Remark 9.** 1. If a point \( x \in X \) is uniformly comparable with \( y \in Y \) by the character of recurrence, and \( y \) is stationary (respectively, \( \tau \)-periodic, almost periodic, almost automorphic, recurrent, Poisson stable), then so is the point \( x \) (see [23–26]).

2. Every almost periodic point is recurrent.

Let \((X, \mathcal{S}_+, \pi), (Y, \mathcal{S}, \sigma), h)\) be a nonautonomous dynamical system. Recall that a mapping \( \zeta : Y \to X \) is called a section (selector) of the homomorphism \( h \), if \( h(\gamma(y)) = y \) for all \( y \in Y \). The section \( \zeta \) of the homomorphism \( h \) is invariant if \( \zeta(\sigma(t, y)) = \pi(t, \zeta(y)) \) for all \( y \in Y \) and \( t \in \mathcal{S}_+ \).
Let $Y$ be a compact metric space. Consider a nonautonomous dynamical system $(X, S_+) = (S, Y, X)$ and denote by $\Gamma(Y, X)$ the family of all continuous sections of the homomorphism $h$. By the equality

$$d(\varphi_1, \varphi_2) := \max_{y \in Y} \rho(\varphi_1(y), \varphi_2(y)),$$

it is defined a metric on $\Gamma(Y, X)$.

Remark 10. A continuous section $\zeta \in \Gamma(Y, X)$ is invariant if and only if $\zeta \in \Gamma(Y, X)$ is a stationary point of the semigroup $\{S^t \mid t \in \mathbb{N}_+\}$, where $\mathcal{S}^t : \Gamma(Y, X) \to \Gamma(Y, X)$ is defined by $\mathcal{S}^t(\zeta) := \pi(t, \zeta(t))$ for all $y \in Y$ and $t \in \mathbb{N}_+$.

Let $(X, T, \pi)$, $(Y, T, \sigma)$, $(h, \varphi)$ be a linear nonautonomous dynamical system. A nonautonomous dynamical system $(X, T, \pi)$, $(Y, T, \sigma)$, $(h, \varphi)$ is said to be linear nonhomogeneous, generated by the linear (homogeneous) dynamical system $(X, T, \pi)$, $(Y, T, \sigma)$, $(h, \varphi)$, if the following conditions hold:

1. There exits a homomorphism $q$ of the dynamical system $(Z, T, \lambda)$ onto $(Y, T, \sigma)$;
2. The space $W_y := (q \circ \rho)^{-1}(y)$ is affine for all $y \in (q \circ \rho)(W) \subseteq Y$ and the vectorial space $Y_y = h^{-1}(y)$ is an associated space to $W_y$ ([22, p.175]). The mapping $\mu(t, \cdot) : W_y \to W_{\sigma(t,y)}$ is affine and $\pi(t, \cdot) : Y_{\sigma(t,y)} \to X_{\sigma(t,y)}$ is its linear associated function ([22, p.179]), i.e. $X_y = \{w_1 - w_2 \mid w_1, w_2 \in W_y\}$ and $\mu(t, w_1) - \mu(t, w_2) = \pi(t, (w_1 - w_2))$ for all $w_1, w_2 \in W_y$ and $t \in T$.

Example 5.1. Let $(E, \varphi, (Y, S, \sigma))$ be a linear cocycle (shortly, $\varphi$), and $(X, S_+, \pi)$, $(Y, S, \sigma)$ be the nonautonomous dynamical system generated by the cocycle $\varphi$. For each $f \in C(Y, E)$ we consider a mapping $\phi_f : S_+ \times E \times Y \to E$ defined by equality

$$\phi_f(t, u, y) := \varphi(t, u, y) + \int_0^t \varphi(t, s, f(s, y), \sigma(s, y)) ds.$$  

(13)

Note that $\phi_f$ is a cocycle. Denote by $(X, S_+, \pi_f)$, $(Y, S, \sigma)$ the nonautonomous dynamical system generated by the cocycle $\phi_f$ (i.e., $X := E \times Y$, $\pi_f := (\phi_f, \sigma)$ and $h := pr_2 : X \to Y$). It is easy to check that $(X, S_+, \pi_f)$, $(Y, S, \sigma)$, $h$ is a linear nonhomogeneous dynamical system, generated by the linear dynamical system $(X, S_+, \pi)$, $(Y, S, \sigma)$ by the linear cocycle $\varphi$ and the function $f \in C(Y, E)$.

Remark 11. 1. If the time is discrete, i.e. $S = \mathbb{Z}$, then it is necessary to write a sum in equality (13) instead of an integral.
2. Note that $\zeta \in \Gamma(Y, X)$ is a continuous section of the nonautonomous dynamical system $(X, S_+, \pi)$, $(Y, S, \sigma)$, $h$, generated by cocycle $(E, \varphi, (Y, S, \sigma))$, if and only if $\zeta = (\nu, Id_Y)$ and $\nu(\sigma(t, y)) = \varphi(t, \nu(y), y)$ for all $t \in S$ and $y \in Y$, where $\nu \in C(Y, E)$. In this case, the function $\nu$ is called a continuous invariant section of the cocycle $\varphi$.

The next theorems establish conditions which ensure the existence of invariant sections.

Theorem 5.2. (See [10, ChII]) Assume that the following conditions hold:

(i) $\Gamma(Z, W) \neq \emptyset$;
(ii) $(X, S_+, \pi)$, $(Y, S, \sigma)$, $h$ is a linear homogeneous dynamical system;
(iii) $(W, S_+, \mu)$, $(Z, S, \lambda)$, $\varrho$ is a linear nonhomogeneous dynamical system generated by $(X, S_+, \pi)$, $(Y, S, \sigma)$, $h$);
(iv) $q$ is a homomorphism from $(Z, S, \lambda)$ onto $(Y, S, \sigma)$;
(v) The spaces $Y$ and $Z$ are compact, and $(X,h,Y)$ is a normed fiber bundle;
(vi) There are two positive numbers $N$ and $ν$ such that
\[ |π(t,x)| ≤ Ne^{-νt}|x| \]
for all $x ∈ X$ and $t ∈ S_+$, i.e., the linear nonautonomous dynamical system
$⟨(X,S_+,π),(Y,S,σ),h⟩$ is uniformly exponentially stable.

Then, the dynamical system $⟨(W,S_+,μ),(Z,S,λ),φ⟩$ admits a unique invariant section $ζ ∈ Γ(Z,W)$.

**Theorem 5.3.** Suppose that the following conditions are satisfied:
(i) The dynamical system $(Y,S,σ)$ is compact and minimal.
(ii) The cocycle $φ$ is nonexpanding.
(iii) The linear nonautonomous dynamical system $⟨(X,S_+,π),(Y,S,σ),h⟩$ is generated by cocycle $φ$.
(iv) The dynamical system $(X,S_+,π)$ is asymptotically compact.

Then, one of the following alternatives is fulfilled:

- a. There is at least one entire recurrent trajectory $ζ$ of $(X,S_+,π)$ with constant positive norm.
- b. For every $f ∈ C(Y,E)$ the nonhomogeneous linear cocycle $φ_f$ (see, Example 5.1) admits a unique continuous invariant section $ζ_f ∈ Γ(Y,E)$.

**Proof.** The statements follow directly from Theorem 4.5 and Theorem 5.2. □

6. **Applications.** We will now apply the abstract theory developed in the previous sections to some interesting applications: linear differential equations in Banach spaces, functional-differential equations, and difference equations.

6.1. **Ordinary linear differential equations in a Banach space.** Let $X$ be a real Banach space with the norm $|·|$, and let $X^*$ denote its dual space with the dual norm also denoted by $|·|$. The value of $f ∈ X^*$ at the point $x ∈ X$ will be denoted by $⟨x,f⟩$. Let $J : X → X^*$ be the duality mapping between $X$ and $X^*$ (see [29]), i.e., for $x ∈ X$, $J(x) := \{f ∈ X^* | ⟨x,f⟩ = |x|^2 = |f|^2\}$.

**Definition 6.1.** The mapping $F : X → X$ is called dissipative, if for any $x,y ∈ X$,
\[ ⟨F(x) − F(y),f⟩ ≤ 0 \]
for all $f ∈ J(x − y)$.

If $X$ is a Hilbert space, then for any $x ∈ X$, $J(x) = x$, hence (14) becomes
\[ ⟨F(x) − F(y),x − y⟩ ≤ 0 \]
for $x,y ∈ X$.

**Lemma 6.2.** (See [14]) Let $(Y,\mathbb{R},σ)$ be a dynamical system, and let $F : Y × X → X$ be a continuous function, and for each $y ∈ Y$ the partial mapping $F(y,·) : X → X$ is dissipative in $x$. If $x_1(t)$ and $x_2(t)$ are two solutions on the interval $(a,b) ⊆ \mathbb{R}$ of the equation
\[ x' = F(σ(t,y),x) \quad (y ∈ Y), \]
then
\[ |x_1(t) − x_2(t)| ≤ |x_1(s) − x_2(s)|, \]
for $a ≤ s ≤ t ≤ b$. 
Let $Y$ be a compact metric space and $(Y, \mathbb{R}, \sigma)$ be a minimal dynamical system (i.e., every trajectory of $(Y, \mathbb{R}, \sigma)$ is dense in $Y$). Consider the equation

$$u' = A(\sigma(t, y))u, \quad (y \in Y) \tag{15}$$

where $A \in C(Y, [E])$. Denote by $\varphi(t, u, y)$ the unique solution of equation (15) passing through the point $u \in E$ at the initial moment $t = 0$. It is well known (see, for example, [10, 5, 21]) that $(E, \varphi, (Y, \mathbb{R}, \sigma)$ is a linear cocycle.

As a straightforward consequence of Lemma 6.2 we have the following result.

**Corollary 6.3.** Let $E$ be a Hilbert space and

$$\langle A(y)u, u \rangle \leq 0$$

for all $u \in E$ and $y \in Y$ (i.e., the operator-function $A \in C(Y, [E])$ is dissipative). Then, the linear cocycle $\varphi$, generated by equation (15), is nonexpanding.

Applying our general results, obtained in Sections 4 and 5 (namely, Corollary 4.6 and Theorem 5.3), to the linear cocycle $\varphi$, we will obtain the following results.

**Theorem 6.4.** Suppose that the following conditions are satisfied:

(i) The dynamical system $(Y, \mathbb{R}, \sigma)$ is compact and minimal.

(ii) The operator-function $A \in C(Y, [E])$ is dissipative.

(iii) The linear cocycle $\varphi$, generated by equation (15), is asymptotically compact.

Then, one of the following alternatives is fulfilled:

a. For every $y \in Y$, equation (15) admits at least one recurrent solution with constant positive norm.

b. The trivial solution of equation (15) is uniformly exponentially stable, i.e., there exist two positive numbers $N$ and $\nu$ such that $|\varphi(t, u, y)| \leq Ne^{-\nu t}|u|$ for all $(u, y) \in X$ and $t \in \mathbb{R}^+$.

**Theorem 6.5.** Assume the following hypotheses:

(i) The dynamical system $(Y, \mathbb{R}, \sigma)$ is compact and minimal.

(ii) The operator-function $A \in C(Y, [E])$ is dissipative.

(iii) The linear cocycle $\varphi$, generated by equation (15), is asymptotically compact.

Then, one of the following alternatives is fulfilled:

a. For every $y \in Y$, equation (15) admits at least one recurrent solution with constant positive norm.

b. For every $f \in C(Y, E)$, there exists a unique function $\nu_f \in C(Y, E)$ such that

$$\phi_f(t, \nu_f(y), y) = \nu_f(\sigma(t, y))$$

for all $t \in \mathbb{R}$ and $y \in Y$, where $\phi_f(t, u, y)$ is a unique solution of the equation

$$v' = A(\sigma(t, y))v + f(\sigma(t, y)) \quad (y \in Y) \tag{16}$$

passing through the point $u \in E$ at the initial moment $t = 0$.

**Corollary 6.6.** Under the conditions of Theorem 6.5 if the statement b. holds and the point $y \in Y$ is quasi-periodic (respectively, almost periodic, almost automorphic, recurrent), then the solution $\varphi(t, \nu(y), y) = \nu(\sigma(t, y))$ of equation (16) is quasi-periodic (respectively, almost periodic, almost automorphic, recurrent).

**Remark 12.** 1. When the space $E$ is finite dimensional, and the dynamical system $(Y, \mathbb{R}, \sigma)$ is almost periodic, Theorem 6.5 generalizes and precises Theorem 3.4 from [12].
2. Note that, under the conditions of Theorem 6.5, if \((Y, \mathbb{R}, \sigma)\) is an almost periodic minimal set we cannot state (in item a.) that there exists at least one almost periodic solution with constant positive norm. This fact is confirmed by the following example.

**Example 6.7.** Consider the almost periodic function

\[
f(t) := \sum_{k=0}^{\infty} \frac{1}{(2k+1)^{3/2}} \sin \frac{t}{2k+1}
\]

and its primitive

\[
F(t) := \int_0^t a(s)ds = \sum_{k=0}^{\infty} \frac{2}{(2k+1)^{1/2}} \sin^2 \frac{t}{2(2k+1)}.
\]

Note that \(F(t)\) is unbounded. Indeed, using the inequality \(|\sin t| \geq \frac{1}{2}|t|\) with \(|t| \leq 1\), we obtain that

\[
F(t) = \sum_{k=0}^{\infty} \frac{1}{(2k+1)^{1/2}} \sin^2 \frac{t}{2(2k+1)} \geq \sum_{k=\frac{1}{2}(\frac{m}{2}+1)}^{\infty} \frac{t^2}{8} \frac{1}{(2k+1)^{5/2}}
\]

\[
\geq \frac{t^2}{8} \int_{|s| \geq \frac{1}{2}(\frac{m}{2}+1)} \frac{ds}{(2s+1)^{5/2}} = \frac{t^22^{3/2}}{24|t|^{5/2}} = \frac{1}{6\sqrt{2}} |t|^{1/2} \to +\infty
\]

as \(|t| \to +\infty\).

Denote by \(Y := H(f)\), where \(H(f)\) is the closure in \(C(\mathbb{R}, \mathbb{R})\) of the family of all shifts \(\{f_\tau : \tau \in \mathbb{R}\}\) \((f_\tau(t) := f(t + \tau)\) for all \(t \in \mathbb{R}\)) Let \((Y, \mathbb{R}, \sigma)\) be a shift dynamical system on \(H(f)\) as a restriction of the Bebutov dynamical system \((C(\mathbb{R}, \mathbb{R}), \mathbb{R}, \sigma)\) on the closed invariant subset \(H(f) \subset C(\mathbb{R}, \mathbb{R})\). Now, consider the equation

\[
u' = \mathcal{F}(\sigma(t,g))u, \quad (g \in H(f), \ u \in \mathbb{R}^2)
\]

(17)

where \(\mathcal{F} \in C(H(f), [\mathbb{R}^2])\) is the function \(\mathcal{F}\) defined as

\[
\mathcal{F}(g) = \begin{pmatrix}
0 & -g(0) \\
g(0) & 0
\end{pmatrix}.
\]

Then, the equation can be rewritten as follows

\[
\begin{cases}
x' = -g(t)y \\
y' = g(t)x
\end{cases}
\]

(18)

where \(g \in H(f)\). Note that \(\langle \mathcal{F}(g)u, u \rangle = -g(0)xy + g(0)xy = 0\) for all \(u = (x, y) \in \mathbb{R}^2\) and \(g \in H(f)\) and, consequently, Theorem 6.5 can be applied to equation (17).

Let \(\varphi(t, x_0, y_0, g)\) be the unique solution of equation (17) with initial condition \(\varphi(0, x_0, y_0, g) = (x_0, y_0) \in \mathbb{R}^2\). Since

\[
\frac{d(x^2(t) + y^2(t))}{dt} = 2x'(t)x(t) + 2y'(t)y(t) = 2(-g(t))y(t) + 2g(t)x(t)y(t) = 0
\]

for all \(t \in \mathbb{R}\) and, consequently, for every nontrivial solution \(\varphi(t, x_0, y_0, g)\) of equation (17) (respectively, of system (18)) we have \(|\varphi(t, x_0, y_0, g)|^2 = x_0^2 + y_0^2\) for all \(t \in \mathbb{R}\). These solutions are recurrent thanks to Theorem 4.5.

Consider the two-dimensional system of differential equations

\[
\begin{cases}
x' = -f(t)y \\
y' = f(t)x
\end{cases}
\]

(19)
which is included in the family (18) because \( f \in H(f) \). The system (19) has no nontrivial almost periodic solutions [5, Ch.IV,pp.269-270].

Let \((Y, \mathbb{R}, \sigma)\) be a compact minimal dynamical system.

We will say that the dynamical system \((Y, \mathbb{R}, \sigma)\) satisfies the condition (C), if for any Banach space \(F\) and any continuous function \(\mathcal{F} \in C(Y, F)\) there exists

\[
M(y) := \lim_{T \to +\infty} \frac{1}{T} \int_0^T \mathcal{F}(\sigma(t, y)) dt.
\]  

(20)

The dynamical system \((Y, \mathbb{R}, \sigma)\) is said to be **ergodic** (with respect to an invariant measure \(\mu\) on \(Y\)) or \(\mu\)-**ergodic** (see [30]) if for every \(\mu\)-measurable invariant set \(A \subset Y\) one has \(\mu(A) \cdot \mu(Y \setminus A) = 0\), that is, either \(A\) or its complement has \(\mu\)-measure zero.

**Remark 13.** 1. If the dynamical system \((Y, \mathbb{R}, \sigma)\) is uniquely ergodic (i.e. there exists a unique normalized invariant measure \(\mu\) on the space \(Y\) and the dynamical system \((Y, \mathbb{R}, \sigma)\) is \(\mu\)-ergodic), then (see [30])

(i) The dynamical system \((Y, \mathbb{R}, \sigma)\) satisfies the condition (C);

(ii) The function \(M : Y \to F\) appearing in (20) is constant;

(iii) The convergence in (20) is uniformly with respect to \(y \in Y\).

2. If the dynamical system \((Y, \mathbb{R}, \sigma)\) is almost periodic, then, there exists a unique invariant measure \(\mu\) on the space \(Y\), and \((Y, \mathbb{R}, \sigma)\) is \(\mu\)-ergodic.

We can now prove the following results.

**Lemma 6.8.** Let \(E\) be a Hilbert space with scalar product \((\cdot, \cdot)\). Assume the following conditions:

(i) \(A \in C(Y, [E])\);

(ii) The operator \(A(y)\) is self-adjoint for all \(y \in Y\);

(iii) \(A(y) \geq 0\) for all \(y \in Y\), i.e., \(\langle A(y)u, u \rangle \geq 0\);

(iv) The operator \(\int_0^h A(\sigma(t, y)) dt\) is invertible.

Then, \(|\varphi(h, u, y)| < |u|\) for all \(u \in E\) with \(|u| \neq 0\) and \(y \in Y\), where \(\varphi(t, u, y)\) is the unique solution of equation (15) with initial condition \(\varphi(0, u, y) = u\).

**Proof.** We argue by contradiction. Suppose that the statement is not true. Then, there exist \(y_0 \in Y\) and \(u_0 \in E\) with \(|u_0| \neq 0\) such that \(|\varphi(h, u_0, y_0)| = |u_0|\). Since

\[
\frac{d}{dt} |\varphi(t, u_0, y_0)|^2 = 2 \langle \varphi'(t, u_0, y_0), \varphi(t, u_0, y_0) \rangle = 2 \langle A(\sigma(t, y_0)) \varphi(t, u_0, y_0), \varphi(t, u_0, y_0) \rangle \leq 0,
\]

for all \(t \in [0, h]\) and, it follows that \(\langle A(\sigma(t, y_0)) \varphi(t, u_0, y_0), \varphi(t, u_0, y_0) \rangle \equiv 0\) on \([0, h]\). Since \(A'(y) = A(y) \geq 0\) for all \(y \in Y\), we have \(A(\sigma(t, y_0)) \varphi(t, u_0, y_0) \equiv 0\) which implies the equality \(\varphi'(t, u_0, y_0) = 0\) for all \(t \in [0, h]\). Thus \(\varphi(t, u_0, y_0) \equiv u_0\) on \([0, h]\) and consequently, \(\int_0^h A(\sigma(t, y_0)) dt u_0 = 0\). Since the operator \(\int_0^h A(\sigma(t, y)) dt\) is invertible we obtain \(u_0 = 0\). This contradiction proves our statement.

**Theorem 6.9.** Let \(E\) be a Hilbert space. Assume that the following conditions are satisfied:

(i) \(A \in C(Y, [E])\);

(ii) The dynamical system \((Y, \mathbb{R}, \sigma)\) is uniquely ergodic;
(iii) The operator
\[ M(y) := \lim_{T \to +\infty} \frac{1}{2T} \int_{-T}^{T} A(\sigma(t,y)) dt \]

is invertible;
(iv) The operator \( A(y) \) is self-adjoint for all \( y \in Y \);
(v) \( A(y) \geq 0 \) for all \( y \in Y \);
(vi) The linear cocycle \( \varphi \), generated by equation (15), is asymptotically compact. Then, the linear cocycle \( \varphi \) is uniformly asymptotically stable.

Proof. Thanks to Theorem 4.5, in order to prove this statement, it is sufficient to show that the sub-bundle \( X^0 \) is trivial. Let \( x \in X^0 \), then there exist \( u_0 \in E \) and \( y_0 \in Y \) such that \( x = (u_0, y_0) \) and \( |\varphi(t, u_0, y_0)| = |u_0| \) for all \( t \in \mathbb{R} \). As the dynamical system \((Y, \mathbb{R}, \sigma)\) is almost periodic, and the operator \( M \in [E] \) is invertible, the operator \( \int_{0}^{h} A(\sigma(t,y_0)) dt \) is also invertible for all sufficiently large \( h > 0 \). From Lemma 6.8 it follows that the equality \( |\varphi(t, u_0, y_0)| = |u_0| \) (for all \( t \in \mathbb{R} \)) takes place only if \( u_0 = 0 \). The theorem is proved.

Corollary 6.10. Let \( E \) be a Hilbert space. Assume that the following conditions hold:
(i) \( A \in C(Y, [E]) \);
(ii) The dynamical system \((Y, \mathbb{R}, \sigma)\) is uniquely ergodic;
(iii) The operator
\[ M(y) := \lim_{T \to +\infty} \frac{1}{2T} \int_{-T}^{T} A(\sigma(t,y)) dt \]

is invertible;
(iv) The operator \( A(y) \) is self-adjoint for all \( y \in Y \);
(v) \( A(y) \geq 0 \) for all \( y \in Y \);
(vi) The linear cocycle \( \varphi \), generated by equation (15), is asymptotically compact. Then, for all \( f \in C(Y, E) \) there exists a unique function \( \nu_f \in C(Y, E) \) such that \( \phi_f(t, \nu_f(y), y) = \nu_f(\sigma(t,y)) \) for all \( t \in \mathbb{R} \) and \( y \in Y \), where \( \phi_f \) denotes the cocycle generated by the linear nonhomogeneous equation (16).

Proof. This statement follows from Theorem 6.9 and 6.5.

Corollary 6.11. Under the conditions of Corollary 6.10, if the point \( y \in Y \) is quasi-periodic (respectively, almost periodic, almost automorphic, recurrent), then the solution \( \phi_f(t, \nu_f(y), y) = \nu_f(\sigma(t,y)) \) of equation (16) is quasi-periodic (respectively, almost periodic, almost automorphic, recurrent).

6.2. Linear functional differential equations with finite delay. Let \( r > 0 \), \( C([a, b], \mathbb{R}^n) \) be the Banach space of all continuous functions \( \varphi : [a, b] \to \mathbb{R}^n \) with the sup-norm. For \( [a, b] := [-r, 0] \), we set \( C := C([-r, 0], \mathbb{R}^n) \). Let \( c \in \mathbb{R}, a \geq 0 \), and \( u \in C([c-r, c+a], \mathbb{R}^n) \). We define \( u_t \in C \), for any \( t \in [c, c+a] \) by the relation \( u_t(\theta) := u(t+\theta), -r \geq \theta \geq 0 \). Let \( \mathfrak{A} = \mathfrak{A}(C, \mathbb{R}^n) \) be the Banach space of all linear operators from \( C \) to \( \mathbb{R}^n \) equipped with the operator norm. Let \( C(\mathbb{R}, \mathfrak{A}) \) be the space of all operator-valued functions \( A : \mathbb{R} \to \mathfrak{A} \) with the compact-open topology, and let \( (C(\mathbb{R}, \mathfrak{A}), \mathbb{R}, \sigma) \) be the dynamical system of shifts on \( C(\mathbb{R}, A) \). Let \( H(A) := \{ A_\tau \mid \tau \in \mathbb{R} \} \), where \( A_\tau \) is the shift of the operator-valued function \( A \) by \( \tau \), and the bar denotes closure in \( C(\mathbb{R}, \mathfrak{A}) \).
Example 6.12. Consider the linear functional-differential equation with delay
\[ u' = A(\sigma(t,y))u, \quad (y \in Y) \] (22)
where \( A \in C(Y, \mathfrak{A}) \).

Remark 14. 1. Denote by \( \tilde{\varphi}(t, u, y) \) the solution of equation (22) defined on \( \mathbb{R}^+ \) (respectively, on \( \mathbb{R} \)) with the initial condition \( \varphi(0, u, y) = u \in C \), i.e., \( \varphi(s, u, y) = u(s) \) for all \( s \in [-r, 0] \). By \( \varphi(t, u, y) \) we will denote below the trajectory of equation (22), corresponding to the solution \( \tilde{\varphi}(t, u, y) \), i.e., the mapping from \( \mathbb{R}^+ \) (respectively, \( \mathbb{R} \)) into \( C \), defined by \( \varphi(t, u, f)(s) := \tilde{\varphi}(t + s, u, f) \) for all \( t \in \mathbb{R}^+ \) (respectively, \( t \in \mathbb{R} \)) and \( s \in [-r, 0] \).

2. Taking into account item 1. of this remark, we use the notions “solution” and “trajectory” for equation (22) as synonyms.

Let \( \varphi(t, u, y) \) be the solution of equation (22) satisfying the condition \( \varphi(0, u, y) = u \) and defined for all \( t \geq 0 \). Let \( X := C \times Y \) and let \( \pi := (\varphi, \sigma) \) be the dynamical system on \( X \) defined by the equality \( \pi(\tau, (u, y)) := (\varphi(\tau, u, y), \sigma(\tau, y)) \). It is easy to see that the nonautonomous system \( \left((X, \mathbb{R}^+), (Y, \mathbb{R}, \sigma), h\right) \) (where \( h := pr_2 : X \to Y \)) is linear.

Lemma 6.13. (See [10, Ch.12]) Let \( Y \) be compact. Then, the linear nonautonomous dynamical system \( \left((X, \mathbb{R}^+), (Y, \mathbb{R}, \sigma), h\right) \) generated by equation (22) is completely continuous, that is, for any bounded set \( A \subseteq X \) there is an \( l = l(A) > 0 \) such that \( \pi(l, A) \) is relatively compact.

Lemma 6.14. Suppose that the following conditions are fulfilled:
(i) The space \( Y \) is compact;
(ii) \( A \in C(Y, \mathfrak{A}) \);
(iii) The operator function \( A : Y \to \mathfrak{A} \) is dissipative, i.e.,
\[ \langle A(y)\phi, \phi(0) \rangle \leq 0 \] (23)
for all \( y \in Y \), and \( \phi \in C \).

Then, the linear cocycle, generated by equation (22), is nonexpanding, i.e.,
\[ ||\varphi(t, u, y)|| \leq ||u|| \quad \text{for all} \quad t \geq 0, \quad u \in C \quad \text{and} \quad y \in Y. \]

Proof. Let \( \tilde{\varphi}(t, u, y) \) be the solution of equation (22) defined on \( \mathbb{R}^+ \) (respectively, on \( \mathbb{R} \)), and denote by \( \tilde{\alpha}(t) := ||\varphi(t, u, y)||^2 \) for all \( t \in \mathbb{R}^+ \) (respectively, for all \( t \in \mathbb{R} \)). Then, from (23) we have
\[ \frac{d\tilde{\alpha}(t)}{dt} = 2\langle A(\sigma(t,y))\varphi(t, u, y), \tilde{\varphi}(t, u, y) \rangle \leq 0, \]
for all \( t \in \mathbb{R}^+ \) (respectively, \( t \in \mathbb{R} \)) and, consequently, we obtain
\[ \tilde{\alpha}(t_2) \leq \tilde{\alpha}(t_1), \] (24)
for all \( t_1, t_2 \in \mathbb{R}^+ \) (respectively, \( t_1, t_2 \in \mathbb{R} \)) with \( t_2 \geq t_1 \). Note that from (24) we have
\[ ||\varphi(t, u, y)|| = \max_{-r \leq s \leq 0} |\tilde{\varphi}(t + s, u, y)| =
|\tilde{\varphi}(t + s, u, y)| \leq |\tilde{\varphi}(s, u, y)| \leq ||u||, \]
for all \( t \geq 0, \ y \in Y \) and \( u \in C \), where \( s_t \) is some number (depending on \( t \)) in the segment \([-r, 0]\). The proof is now complete.
Applying our general results (namely, Theorem 4.5, Corollary 4.6 and Lemma 6.14) to the linear cocycle $\varphi$, generated by equation (22), we will obtain the following results.

**Theorem 6.15.** Assume the following conditions:

(i) The dynamical system $(Y, \mathbb{R}, \sigma)$ is compact and minimal.

(ii) The operator-function $A \in C(Y, \mathbb{R})$ is dissipative.

Then, one of the following alternatives is fulfilled:

a. For every $y \in Y$, equation (22) admits at least one recurrent solution with constant positive norm.

b. The trivial solution of equation (22) is uniformly exponentially stable, i.e., there exist two positive numbers $N$ and $\nu$ such that $|\varphi(t, u, y)| \leq Ne^{-\nu t}|u|$ for all $(u, y) \in X$ and $t \in \mathbb{R}_+$.

**Proof.** Let $\varphi$ be the cocycle generated by Eq. (22), and $\langle (X, \mathbb{R}_+, \pi), (Y, \mathbb{R}_+, \sigma), h \rangle$ the linear nonautonomous dynamical system associated to $\varphi$ (see Example 6.12). According to Lemma 6.13, the dynamical system $(X, \mathbb{R}_+, \pi)$ is completely continuous and, in particular, the cocycle is asymptotically compact. Now, to finish the proof, it is sufficient to apply Theorem 4.5 and Corollary 4.6.

**Theorem 6.16.** Assume the following conditions:

(i) The dynamical system $(Y, \mathbb{R}, \sigma)$ is compact and minimal.

(ii) The operator-function $A \in C(Y, \mathbb{R})$ is dissipative.

Then, one of the following alternatives is fulfilled:

a. For every $y \in Y$, equation (22) admits, at least, one recurrent solution with constant positive norm.

b. For every $f \in C(Y, \mathbb{R})$, there exists a unique function $\nu_f \in C(Y, \mathbb{C})$ such that

$$\phi_f(t, \nu_f(y), y) = \nu_f(\sigma(t, y))$$

for all $t \in \mathbb{R}$ and $y \in Y$, where $\phi_f(t, u, y)$ is the unique solution of the equation

$$v' = A(\sigma(t, y))v + f(\sigma(t, y)) \quad (y \in Y)$$

passing through the point $u \in \mathbb{C}$ at the initial moment $t = 0$.

**Proof.** This statement can be proved in the same way as Theorem 6.15, but instead of Theorem 4.5 and Corollary 4.6, we need to apply Theorem 5.3.

**Corollary 6.17.** Under the conditions of Theorem 6.16, if the statement b. holds and the point $y \in Y$ is quasi-periodic (respectively, almost periodic, almost automorphic, recurrent), then the solution $\phi_f(t, \nu_f(y), y) = \nu_f(\sigma(t, y))$ of equation (25) is quasi-periodic (respectively, almost periodic, almost automorphic, recurrent).

### 6.3. Difference equations.

Let us now apply our general theory to some applications from the theory of difference equations.

Let $(Y, \mathbb{Z}, \sigma)$ be a dynamical system with discrete time $\mathbb{Z}$ on the compact metric space $Y$. Consider the difference equation

$$x(n + 1) = A(\sigma(n, y))x(n), \quad (y \in Y)$$

where $A \in C(Y, [E])$.

Denote by $\varphi(n, u, y)$ the unique solution of equation (26) with initial data $\varphi(0, u, y) = u$. It is well known (see, for example, [5, 10, 21]) that the triplet $\langle E, \varphi, (Y, \mathbb{Z}, \sigma) \rangle$
is a linear cocycle over \((Y, Z, \sigma)\) with discrete time. Let \((X, Z^+, \pi)\) be the corresponding skew-product dynamical system (i.e., \(X := E \times Y\) and \(\pi := (\varphi, \sigma)\)) and \(\langle X, Z^+, \pi \rangle, (Y, Z, \sigma), h \rangle\) be the nonautonomous dynamical system generated by the cocycle \(\varphi\), where \(h := p^{r_2}\).

**Remark 15.**
1. Consider the difference equation
\[
x(n + 1) = A(n)x(n),
\]
where \(A \in C(Z, [E])\). Along with equation (27), we consider a family of equations
\[
y(n + 1) = B(n)y(n),
\]
where \(B \in H(A) := \{A_m | m \in Z\}\), \(A_m\) is \(m\) shift of operator \(A\) (i.e., \(A_m(n) := A(n + m)\) for all \(n \in Z\)) and by \(\bar{A}\) we denote the closure on the space \(C(Z, [E])\) which is endowed with the compact-open topology. The family of equations (28) can be written in the form (26). Indeed, let \(Y = H(A)\) and by \((Y, Z, \sigma)\) we denote the shift dynamical system on \(H(A)\). Now we can rewrite the family of equations (27) as follow
\[
x(n + 1) = \bar{A}(\sigma(n, y))x(n), \quad (y \in Y)
\]
where \(\bar{A} : H(A) \to [E]\) is the mapping defined by the equality \(\bar{A}(B) := B(0)\), for all \(B \in H(A)\).

2. Note that \(H(A)\) is a compact minimal set (of the Bebutov dynamical system \((C(Z, [E]), Z, \sigma)\)) if and only if the operator-function \(A \in C(Z, [E])\) is recurrent with respect to \(n \in Z\) (in particular, almost periodic or almost automorphic).

Applying our general results from Sections 4 and 5, we will be able to obtain some new and interesting results for the difference equation (26).

Namely, the following results hold.

Recall that an operator \(A \in C(Y, [E])\) is said to be **completely continuous**, if, for any bounded subset \(B \subset E\), the set \(\bigcup \{A(y)B : y \in Y\}\) is relatively compact.

**Remark 16.** It is clear that if the space \(E\) is finite-dimensional and \(Y\) is compact, then, every operator \(A \in C(Y, [E])\) is completely continuous.

**Definition 6.18.** An operator \(A \in C(Y, [E])\) is said to be asymptotically compact, if there are \(A', A'' \in C(Y, [E])\) such that

(i) \(A(y) = A'(y) + A''(y)\) for all \(y \in Y\);
(ii) For all \(y \in Y\), the operator \(A'(y)\) is a contraction, i.e., \(||A'(y)|| < 1\);
(iii) For every \(y \in Y\), the operator \(A''(y)\) is compact (completely continuous).

**Lemma 6.19.** Suppose that the following conditions are fulfilled:

(i) The space \(Y\) is compact;
(ii) The operator \(A \in C(Y, [E])\) is asymptotically compact.

Then, the cocycle \(\varphi\), generated by equation (26), is asymptotically compact.

**Proof.** Let \(\varphi\) be the cocycle generated by equation (26). Then,

\[
\varphi(n, u, y) = A(\sigma(n, y))A(\sigma(n - 1, y)) \ldots A(\sigma(1, y))A(y)u
\]

for all \(y \in Y, n \in Z^+_+\) and \(u \in E\). Denote by

\[
\varphi_1(n, u, y) := A'(\sigma(n, y))A'(\sigma(n - 1, y)) \ldots A'(\sigma(1, y))A'(y)u
\]

and \(\varphi_2(n, u, y) := \varphi(n, u, y) - \varphi_1(n, u, y)\). Thanks to our assumptions, \(\varphi_1\) and \(\varphi_2\) satisfy the following conditions:
(i) $|\varphi_1(n, u, y)| \leq \alpha^n|u|$ for all $n \in T_+$ and $(u, y) \in E \times Y$, where

$\alpha := \min\{|\|A(y)\|| : y \in Y\};$

(ii) The set $\varphi_2(n, A, Y)$ is relatively compact for all $n \in \mathbb{N}$, and any bounded subset $A$ from $E$.

Now, to finish the proof, it is sufficient to apply Theorem 3.3 and Lemma 3.4.

**Lemma 6.20.** Suppose that the following conditions are fulfilled:

(i) The space $Y$ is compact;

(ii) $A \in C(Y, \mathbb{E})$ is asymptotically compact;

(iii) $|A(y)| \leq 1$ (29)

for all $y \in Y$, where $|\cdot|$ is the operator norm.

Then,

(i) The linear cocycle, generated by equation (26), is nonexpanding, i.e., $|\varphi(n, u, y)| \leq |u|$ for all $n \in \mathbb{Z}_+$, $u \in E$ and $y \in Y$;

(ii) The cocycle $\varphi$, generated by equation (26), is asymptotically compact.

**Proof.** Let $\varphi(n, u, y)$ be the solution of equation (26). Then,

\[
\varphi(n, u, y) = A(\sigma(n, y))A(\sigma(n - 1, y)) \ldots A(\sigma(1, y))A(y)u
\]

(30)

for all $u \in E$ and $y \in Y$. From equalities (29) and (30) it follows that $|\varphi(n, u, y)| \leq |u|$ for all $n \in \mathbb{Z}_+$ and $(u, y) \in E \times Y$. Thus the first statement of Lemma is proved.

The second statement follows from Lemma 6.19. □

**Theorem 6.21.** Assume the following conditions:

(i) The dynamical system $(Y, Z, \sigma)$ is compact and minimal.

(ii) The operator $A \in C(Y, \mathbb{E})$ is asymptotically compact;

(iii) $|A(y)| \leq 1$ for all $y \in Y$.

Then, one of the following alternatives is fulfilled:

a. For every $y \in Y$, equation (26) admits at least one recurrent solution with constant positive norm.

b. The trivial solution of equation (26) is uniformly exponentially stable, i.e., there exist two positive numbers $N$ and $\nu$ such that $|\varphi(n, u, y)| \leq Ne^{-\nu n}|u|$ for all $(u, y) \in X$ and $t \in \mathbb{Z}_+$.

**Proof.** Let $\varphi$ be the cocycle generated by equation (26), and $\langle (X, Z, \pi), (Y, Z, \sigma), h \rangle$ the linear nonautonomous dynamical system associated to $\varphi$. Since the cocycle $\varphi$ is asymptotically compact, then the dynamical system $(X, Z, \pi)$ is also asymptotically compact. Now, to finish the proof, it is sufficient to apply Theorem 4.5 and Corollary 4.6. □

**Theorem 6.22.** Suppose that the following conditions are fulfilled:

(i) The dynamical system $(Y, Z, \sigma)$ is compact and minimal.

(ii) The operator $A \in C(Y, \mathbb{E})$ is asymptotically compact;

(iii) $|A(y)| \leq 1$ for all $y \in Y$.

Then, one of the following alternatives is fulfilled:

a. For every $y \in Y$, equation (26) admits, at least, one recurrent solution with constant positive norm.
b. For every $f \in C(Y, E)$, there exists a unique function $\nu_f \in C(Y, E)$ such that $\phi_f(n, \nu_f(y), y) = \nu_f(\sigma(n, y))$ for all $t \in \mathbb{Z}$ and $y \in Y$, where $\phi_f(n, u, y)$ is the unique solution of equation $v(n + 1) = A(\sigma(n, y))v(n) + f(\sigma(n, y))$, $\ y \in Y$, (31) passing through the point $u \in E$ at the initial moment $n = 0$.

**Proof.** This statement can be proved as Theorem 6.21, but instead of Theorem 4.5 and Corollary 4.6 we need to apply Theorem 5.3.

**Corollary 6.23.** Under the conditions of Theorem 6.22, if statement b. holds, and the point $y \in Y$ is quasi-periodic (respectively, almost periodic, almost automorphic, recurrent), then the solution $\phi_f(n, \nu_f(y), y) = \nu_f(\sigma(n, y))$ of equation (31) is quasi-periodic (respectively, almost periodic, almost automorphic, recurrent).

**Remark 17.** 1. If the dynamical system $(Y, Z, \sigma)$ is almost periodic (in particular, it is uniquely ergodic), then we have (see, for example, [18, ChIV]):

(i) There exists the limit

$$
\mu := \lim_{n \to \infty} \frac{1}{n} \sum_{k=0}^{n-1} \ln \| A(\sigma(k, y)) \|; 
$$

(ii) This limit exists uniformly with respect to $y \in Y$;

(iii) The limit $\mu$ in (32) does not depend on $y \in Y$.

2. If, under the conditions of Theorem 6.22, we replace (iii) by the condition $\mu < 0$, then, for every $f \in C(Y, E)$, there exists a unique function $\gamma_f \in C(Y, E)$ such that $\phi_f(n, \gamma_f(y), y) = \gamma_f(\sigma(n, y))$ for all $t \in \mathbb{Z}$ and $y \in Y$, where $\phi_f(n, u, y)$ is the unique solution of equation (31), passing through the point $u \in E$ at the initial moment $n = 0$. This fact is a particular case of one result established in our paper [7].
