Numerical analysis of the PSI solution of advection-diffusion problems through a Petrov-Galerkin formulation

Tomás Chacón Rebollo∗, Macarena Gómez Mármol†, Gladys Narbona Reina‡

2nd April 2007

Abstract

In this paper we introduce an analysis technique for the solution of the steady advection-diffusion equation by the PSI (Positive Streamwise Implicit) method. We formulate this approximation as a non-linear finite element Petrov-Galerkin scheme, and use tools of functional analysis to perform a convergence, error and maximum principle analysis. We prove that the scheme is first-order accurate in $H^1$ norm, and well-balanced up to second order for convection-dominated flows. We give some numerical evidence that the scheme is only first order accurate in $L^2$ norm. Our analysis also holds for other non-linear Fluctuation Splitting schemes that can be built from first-order monotone schemes by the Abgrall and Mezine’s technique introduced in [2].

1 Introduction

We revisit in this paper the problem set by the accurate numerical solution of flow problems in advection dominated regimes. It is well known that this is a challenging problem due to the need of combining high-order accuracy at steady state with maximum principle. Both requirements are essential to obtain numerical solutions that are useful for scientific and engineering applications.

This problem has received several ways of solution by means of methods that necessarily must be non-linear, due to Godunov’s Theorem, to comply with both requirements of being of high order at steady state and verifying the maximum principle (See Toro [32]). Let us

mention the method of Characteristics (See Pironneau [24], Suli [30]), and more recently the Discontinuous Galerkin (See Cockburn [11], Cockburn and Shu [12]) and Fluctuation Splitting or Residual Distribution methods.

Fluctuation Splitting methods originated in the work by Roe and Sidilkover where the \( N \) (narrow) scheme was identified as the linear scheme with the smaller numerical diffusion for the solution of transient advection equations on rectangular grids. This scheme was extended to a large class of linear and non-linear compact schemes to solve hyperbolic systems of conservation laws by piecewise affine finite element discretizations on triangular grids by the same authors, and also by Deconinck, Struijs and co-workers (See [13], [21], [28], [29] for instance) and more recently by Abgrall and co-workers (See [1], [2] and [3]).

The convergence of the \( N \) scheme for transient linear advection schemes was analysed by Perthame and co-workers in [22] and [23], where its strong \( L^2 \) convergence was proved. This analysis is based upon an intrinsic interpretation of the \( N \)-scheme as a finite volume scheme, and upon the obtention of weak bounded variation estimates as for the convergence of conservation laws on triangular grids.

One of the most successful non-linear Fluctuation Splitting schemes is the PSI (Positive Streamwise Implicit) method, introduced in [13]. This is an extension of the \( N \)-scheme to second-order for steady state. It is monotone and is particularly accurate in zones of strong gradients or discontinuities of the solution.

Our purpose in this paper is to analyse the solution of the steady advection-diffusion equation when the advection operator is discretized by the PSI method and the diffusion operator is discretized by the standard Galerkin approximation. Our main contribution is to formulate this approximation as a non-linear finite element Petrov-Galerkin scheme, and to use the tools of functional analysis adapted to this kind of formulation to perform a convergence, error and maximum principle analysis.

We consider the advection-diffusion problem in this paper as a model problem, where we introduce the basic aspects of our analysis. This analysis may be used as a basis for several further developments. At first, to analyse the solution of unsteady convection-diffusion problems as an straightforward extension of the present analysis.

Also, the PSI method may be used in the solution of Navier-Stokes equations by piecewise affine Finite Elements, to obtain a positive solver of the convection operator. This yields a robust solver with excellent stability properties. The analysis of this solver so as some relevant numerical tests will appear in a forthcoming paper.

The paper is organised as follows. In Section 2 we set an abstract Petrov-Galerkin discretization for the advection-diffusion equation, satisfying some general hypotheses that are stated in Section 3. Section 4 proves that the PSI and other non-linear Fluctuation Splitting methods may be formulated in the abstract framework set in Section 2. Section 5 develops some technical tools that are used in following Sections to prove existence and quasi-uniqueness results for discrete problems, and in Section 7 to perform a convergence and error analysis. Section 8 is devoted to prove the maximum principle and to obtain \( L^r \)-estimates. Finally, in Section 9 some numerical evidence is given that the PSI method has an overall first order in \( L^r \) norms, while a second order well-balanced property for advection-dominated regimes is proved.
2 The advection-diffusion problem

In this section we introduce an approximation of the stationary advection-diffusion problem by a non-linear Petrov-Galerkin Finite Element method. This will be an abstract discrete variational formulation for the PSI (Positive Streamwise Implicit) method.

Let $\Omega$ be a bounded domain of $\mathbb{R}^d$ ($d = 2$ or $3$) with Lipschitz boundary $\Gamma$. We consider a measurable subset $\Gamma^-$ of $\Gamma$ with non-zero measure, and set $\Gamma^+ = \Gamma \setminus \Gamma^-$. Denote by $n$ the unit normal to $\Gamma$, outer to $\Omega$. We consider the following stationary advection-diffusion problem:

$$
\begin{aligned}
&u \cdot \nabla \rho - \nu \Delta \rho = f & \text{in } \Omega \\
&\rho = g & \text{on } \Gamma^- \\
&\nu \frac{\partial \rho}{\partial n} = 0 & \text{on } \Gamma^+,
\end{aligned}
$$

(1)

where $\rho$ is a physical magnitude (a “tracer”) transported by the velocity field $u : \bar{\Omega} \rightarrow \mathbb{R}^d$, and $\nu$ is the diffusion coefficient of $\rho$. Also, $f : \bar{\Omega} \rightarrow \mathbb{R}^d$ is the source term and $g$ is the Dirichlet data for $\rho$ on the inflow boundary $\Gamma^-$. We assume that the velocity field satisfies $u \in L^q(\Omega)^d$ for some $q > d$ and $\nabla \cdot u = 0$. Then, the trace on $\Gamma$ of the normal velocity $u \cdot n$ belongs to $L^r(\Gamma)^d$, with $r = q(d-1)/d > 1$. This is proved by a duality argument based upon Sobolev’s injections. This allows us to formalize the meaning of “inflow boundary” as $u \cdot n$ is defined a.e. on $\Gamma$. Specifically, we assume

$$u \cdot n < 0 \; \text{a.e. on } \Gamma^-,$$

and $u \cdot n \geq 0 \; \text{a.e. on } \Gamma^+.$

We define the space

$$V = \{v \in H^1(\Omega) / v|_{\Gamma^-} = 0\},$$

and consider the variational formulation of problem (1),

$$\text{Obtain } \rho \in G + V \text{ such that } \quad a(\rho, v) = \langle f, v \rangle \; \forall v \in V,$n

(2)

where $G \in H^1(\Omega)$ is some lifting of $g$ and $a : H^1(\Omega) \times H^1(\Omega) \rightarrow \mathbb{R}$ is the bilinear form

$$a(w, v) = \int_\Omega (u \cdot \nabla w) v + \nu \int_\Omega \nabla w \cdot \nabla v.$$

(3)

Under the above hypotheses on $u$, problem (2) admits a unique solution in $H^1(\Omega)$ if $g \in H^{1/2}(\Gamma^-)$ and $f \in V'$, by Nečas Lemma. (See Ern & Guermond [16].)

We may assume $g = 0$ up to an additive changement of the source term $f$, and we shall assume it so, without loss of generality. In this case the solution $\rho$ belongs to $V$.

To approximate problem (2), let us assume $\Omega$ to be a poligonal domain. Consider a triangulation $T_h$ of $\Omega$ by triangles in 2D and tetrahedra in 3D. As usual we assume that $h$ denotes the largest diameter of the elements of $T_h$. Consider the finite dimensional spaces of piecewise affine finite elements built on $T_h$:

$$V_h^* = \{v_h \in C^0(\bar{\Omega}) / v_{h|T} \in P_1 \; \forall T \in T_h\}, \quad V_h = \{v_h \in V_h^*/ v_h = 0 \; \text{on } \Gamma^-\}.$$n

(4)
Denote by \( \{ b_j \}_{j=1}^M \) the nodes of the mesh located on \( \Omega \setminus \Gamma^- \) and by \( \{ b_j \}_{j=M+1}^N \) those located on \( \Gamma^- \). We consider the nodal basis functions of \( V_h^* \), \( \{ \varphi_i \}_{i=1}^N \) defined by

\[
\varphi_i(b_j) = \delta_{ij}, \quad 1 \leq i, j \leq N.
\]

The nodal base of \( V_h \) is then \( \{ \varphi_i \}_{i=1}^M \).

We also associate to \( T_h \) and a given element \( s_h \) of \( V_h^* \) a discrete space of piecewise constant functions, denoted by \( W_h^*(s_h) \). This space is defined through its *nodal* basis functions \( \lambda_1, \lambda_2, \ldots, \lambda_N \) (also depending on \( s_h \)), that we assume known for the time being:

\[
W_h^*(s_h) = \text{span}\{ \lambda_1(s_h), \lambda_2(s_h), \ldots, \lambda_N(s_h) \}.
\]

For simplicity of notation, we do not explicit the dependence upon \( s_h \) of the \( \lambda_i \) when this is not source of confusion.

We shall use the functions of \( W_h^*(s_h) \) to test the advection operator in equation (8). The functions \( \lambda_j \) have supports that look for “upwind” information with respect to the velocity field \( u \) (See Fig. 1).

The dependence upon \( s_h \) is due to the non-linear nature of the PSI method, which appears under this formulation as the dependency of the constant values that the basis functions \( \lambda_i \) take on each triangle \( T \) of \( T_h \): \( \lambda_i|_T = \lambda_i|_T(s_h) \). In Section 4 we give the definition of the \( \lambda_j \) for PSI and actually other fluctuation splitting methods, although for our analysis we shall only consider some abstract properties that we describe next.
We construct an associated interpolation operator taking values on $W_h^*$, denoted by $\Pi_{s_h}$, as follows:

$$\Pi_{s_h} : C^0(\Omega) \rightarrow W_h^*$$

$$z \rightarrow \Pi_{s_h} z = \sum_{i=1}^{N} z(b_i)\lambda_i.$$  

(6)

Note that if $z \in V_h$, then

$$\Pi_{s_h} z = \sum_{i=1}^{M} z(b_i)\lambda_i \in W_h = \text{span}\{\lambda_1, \lambda_2, \cdots, \lambda_M\}.$$  

Note also that $\lambda_j = \Pi_{s_h} \varphi_j$, $j = 1, 2, \cdots, N$. Thus, $\Pi_{s_h}$ is bijective from $V_h^*$ onto $W_h^*$ and also from $V_h$ onto $W_h$.

We shall refer to $\Pi_{s_h}$ as the Distributed Interpolation operator generated by function $s_h$.

We may characterize each actual Fluctuation Splitting method by its associated Distributed Interpolation operator, through the definition of the basis functions $\lambda_j$.

We define the bilinear form $a_h : V_h \times V_h \mapsto \mathbb{R}$ as

$$a_h(\rho_h, v_h) = \int_{\Omega} (u \cdot \nabla \rho_h) \Pi_{\rho_h} v_h + \nu \int_{\Omega} \nabla \rho_h \cdot \nabla v_h.$$  

(7)

We may now formulate our discrete variational approximation of the advection-diffusion problem (1), as follows:

$$\left\{ \begin{array}{l}
\text{Find } \rho_h \in V_h \text{ such that } \\
a_h(\rho_h, v_h) = \langle f, v_h \rangle \quad \forall \, v_h \in V_h.
\end{array} \right.$$  

(8)

To obtain a more accurate scheme for advection-dominated flows, we may also upwind the source term. This is obtained in a natural way, as follows:

$$\left\{ \begin{array}{l}
\text{Find } \rho_h \in V_h \text{ such that } \\
a_h(\rho_h, v_h) = \langle f, \Pi_{\rho_h} v_h \rangle \quad \forall \, v_h \in V_h.
\end{array} \right.$$  

(9)

The term $\langle f, \Pi_{\rho_h} v_h \rangle$ makes sense for smoother $f$ than $f \in V'$, for instance $f \in L^1(\Omega)$.

3 Hypotheses

We next state the general hypotheses that we assume about our approximation, to perform our error analysis. We prove in Section 4 that the PSI method, and some other non-linear FS schemes, when applied to the solution of the advection-diffusion (1), may be cast as Petrov-Galerkin methods (8) or (9), verifying these hypotheses.

We at first assume the hypotheses related to the approximation properties of the interpolation operator $\Pi_{s_h}$:
Hypothesis 1 For any element $T \in \mathcal{T}_h$,

1. $\lambda^T_{i_T} \geq 0, \quad i = 1, \ldots, d + 1,$

2. $\sum_{i=1}^{d+1} \lambda^T_{i_T} = 1,$ □

where $i_T$ is the global index corresponding to the local index $i_T$, $i = 1, \ldots, d + 1$ on element $T$, and $\lambda^T_{i_T}$ is the restriction of $\lambda_{i_T}$ to element $T$.

These properties yield the stability of the Distribution Interpolation operator (see Section 5).

We next consider additional hypotheses required to obtain the maximum principle. For the discrete problems (8) and (9), we understand this principle in the following sense:

**Maximum Principle:** If $f \geq 0$ in $\Omega$, then $\rho_h \geq 0$ in $\Omega$.

Several authors have performed an extensive analysis about sufficient conditions on the grid that yield the maximum principle for piecewise affine finite element discretizations of elliptic equations, in two and three space dimensions (see Dragănescu, Dupont and Scott [15] and references therein, Varga [33]). These conditions ensure that the matrix associated to the discrete problem is a monotone matrix, i.e., it is non-singular and its inverse has non-negative entries.

Notice that the matrix $A_\nu = A_\nu(s_h)$ associated to problems (8) and (9) is defined as:

$$A_\nu(s_h) = C(s_h) + \nu L,$$

where $C(s_h)$ and $L$, respectively, are the matrices associated to the discretization of the advection and the Laplacian operators. Their coefficients are given by:

$$C_{ij}(s_h) = \int_\Omega (u \cdot \nabla \varphi_j) \Pi_{s_h} \varphi_i = \int_\Omega (u \cdot \nabla \varphi_j) \lambda_i(s_h),$$

$$L_{ij} = \int_\Omega \nabla \varphi_j \cdot \nabla \varphi_i \quad \text{i.e., } A \text{ has diagonal dominance.}$$

Our analysis of the maximum principle is based on a property stronger than monotonicity: We assume $A_\nu(\rho_h)$ to be an M-matrix. We recall that $A$ is an M-matrix if

1. $A_{ii} > 0, \quad \forall 1 \leq i \leq M.$ (10)

2. $A_{ij} \leq 0, \quad \forall 1 \leq i, j \leq M, i \neq j.$ (11)

3. $A_{ii} \geq \sum_{j \neq i} |A_{ij}|, \quad \forall 1 \leq i \leq M \quad \text{i.e., } A \text{ has diagonal dominance.}$ (12)
We shall assume the following hypothesis:

**Hypothesis 2**

\[ A_\nu(s_h) \text{ is a M-matrix, for any } s_h \in V_h \text{ and any } \nu > 0, \]

To ensure that the discrete Laplacian \( L \) is an M-matrix it is enough to ask that all angles between sides (d=2) or all dyhedric angles between faces (d=3) of all elements of the grid are acute or, at most, of \( \pi/2 \) degrees. This is a classical result that may be found for instance in [15].

However, building a advection-diffusion matrix \( A \) which is a M-matrix for any value of the diffusion coefficient \( \nu \) is an achievement of FS methods. We shall prove this in Section 5.

We finally state a technical hypothesis on the dependence of the behaviour of the convective matrix with respect to its argument \( s_h \):

**Hypothesis 3**

The convective matrix \( C(s_h) \) is a continuous function from \( V_h \) onto the space of square real matrices of dimension \( M \times M \).

This Hypothesis is mainly related to the boundedness of the basis functions \( \lambda_j \). It is verified by the PSI scheme and other non-linear FS schemes, but not by positive first-order FS methods, in particular by the N-scheme. This agrees with the interpretation of the N-scheme as a finite volume scheme by Perthame in [23].

### 4 Relationship to Fluctuation Splitting methods

This Section is devoted to prove that methods (8) and (9) are abstract formulations for PSI and other non-linear FS methods applied to the numerical solution of the advection-diffusion problem (1), and that under this characterization, Hypotheses 1, 2 and 3 of Section 3 are verified.

Let us consider that the convective flow of the tracer \( \rho \) transported by the velocity field \( u \) is

\[ q_{\text{conv}} = u\rho. \]

The total balance of convective flow ("fluctuation") through \( \partial T \) for some \( T \in \mathcal{T}_h \) is then

\[ \Phi^T = \int_{\partial T} q_{\text{conv}} \cdot n = \int_T \nabla \cdot (u\rho) = \int_T u \cdot \nabla \rho, \]

where we have used that \( \nabla \cdot u = 0 \).

The basic idea of FS methods is to split the fluctuation \( \Phi^T \) between the vertex neighbouring the element \( T \). This is made by means of some "flux distribution coefficients" \( \{\beta_j^T\}_{j=1}^N \). The fluctuation contribution to vertex \( b_j \) is

\[ \Phi_j = \sum_{T \in \mathcal{T}_h} \beta_j^T \Phi^T. \]
To increase the compactness of the numerical scheme, usually the fluctuation generated in an element $T$ is only sent to the vertex of $T$:

$$\beta_j^T = 0 \quad \text{if } b_j \quad \text{is not a vertex of } T.$$ 

This yields the following discretization for the steady advection equation:

$$\sum_{T \in E_j} \beta_j^T \int_T u \cdot \nabla \rho = \sum_{T \in E_j} \beta_j^T \int_T f, \quad (14)$$

where $E_j$ is the set of elements of $T$ that share the vertex $b_j$.

For a given vertex $b_j$ of the triangulation $T_h$, we define the associated piecewise constant basis function $\lambda_j$ by

$$\lambda_j : \Omega \mapsto \mathbb{R}, \quad \text{with} \quad \lambda_j = \beta_j^T \quad \text{on element } T, \quad \forall \ T \in T_h$$

Then, the l.h.s. of (14) is re-written as

$$\sum_{T \in E_j} \beta_j^T \int_T u \cdot \nabla \lambda_j = \int_{\Omega} u \cdot \nabla \lambda_j,$$

and we recover our Petrov-Galerkin discretization of the advection operator, for the Distribution Interpolation operator associated to these actual $\lambda_j$.

The discretization of the source term in (14) is also re-written as

$$\sum_{T \in E_j} \beta_j^T \int_T f = \int_{\Omega} f \lambda_j.$$

To obtain a flux-conservative and a $L^\infty$-stable method, the following properties are usually assumed (Cf. [2]):

$$\sum_{j=1}^{d+1} \beta_j^T = 1, \quad \beta_j^T \geq 0, \quad \text{for any node } b_j, \quad \text{for any triangle } T \in T_h. \quad (15)$$

This trivially yields our first hypothesis:

**Lemma 4.1** Assume the distribution coefficients verify properties (15). Then, Hypothesis 1 holds.

Our proof that Hypotheses 2 and 3 hold for PSI scheme is based upon the construction of this scheme introduced in Abgrall and Mezine [2]. In its turn, this construction is based upon that of N scheme, which is introduced via the fluctuations

$$\Phi^T_i(s_h) = \beta_i^T \Phi^T(s_h), \quad \text{for } s_h \in V_h$$
sent to the local nodes. To define the $\Phi^T_i$ let us introduce the inward normal vector to the boundary of $T$, opposite to node $b_i$,

$$n^T_i = d|T|\nabla \varphi_{T},$$

and the values

$$K^T_i = \frac{1}{d} \bar{u}^T \cdot n^T_i, \quad \text{with} \quad \bar{u}^T = \frac{1}{|T|} \int_T u.$$ 

Then, the N scheme, when $d = 2$ for simplicity, is given by

$$\Phi^T_i(s_h) = \sum_{i=1}^{3} c_{ij}^T (s^T_i - s^T_j), \quad c_{ij} = (K^T_i)^+ M^T (K^T_j)^-, \quad \beta^T_i = \Phi^T_i,$$

(17)

where $(K^T_i)^+ = \max\{K^T_i, 0\}$, $(K^T_j)^- = \min\{K^T_j, 0\}$, $M^T = \sum_{j=1}^{3} (K^T_j)^-$,

and $s^T_1$, $s^T_2$, $s^T_3$ are the values of $s_h$ at the vertex of $T$ (we use local notation for the index to simplify the notation).

Notice also that $M^T$ is non-zero (in fact, it is strictly negative) if $\bar{u} \neq 0$ as $\sum_{i=1}^{d+1} K^T_i = 0$. Also, that $c_{ij} \geq 0$. This property (called monotonicity) yields the $L^\infty$ stability of the N scheme for evolution systems of conservation laws, under a CFL condition (Cf. [2]).

Note that the sign of $K^T_i$ indicates whether the node $b_i$ is upflow with respect to $u$ in triangle $T$ ($K^T_i \leq 0$). The nodes located upflow cannot receive any fluctuation contribution for FS schemes to be stable.

In some cases, the fluctuation $\Phi^T_i$ could vanish while the partial fluctuation $\Phi^T_i(s_h)$ remains finite, and then the coefficient $\beta^T_i$ is not defined. For this reason, the N scheme does not enter in the framework of our Petrov-Garlekin formulation.

The PSI scheme is constructed in [2] by looking at new fluctuations $\tilde{\Phi}^T_i$ (we drop the superscript T and the explicit dependence upon $s_h$ for simplicity) such that

$$\Phi^*_i = (1 - \mu_i) \Phi^T_i, \quad \text{for some coefficients} \ 0 \leq \mu_i \leq 1, \ i = 1, \cdots, d + 1$$

$$\sum_{i=1}^{d+1} \Phi^*_i = \Phi.$$

(18)  

(19)

The coefficients $\beta^*_i = \frac{\Phi^*_i}{\Phi}$ are bounded independently of the mesh.

(20)

This problem is solved in [2] by means of a constructive solution. It is proved that the $\mu_i$ are continuous functions of the $\Phi^T_i$, and that the $\beta^*_i \in [0, 1]$.

Note that the $\beta^*_i$ are functions of $s_h$, as both $\Phi^*$ and $\Phi$ depend on $s_h$. Moreover, from (19) and the property $\beta^*_i \in [0, 1]$ we recover property (15):

$$\sum_{i=1}^{3} \beta^*_i = 1, \quad \beta^*_i \geq 0.$$
We do not detail the actual construction of the PSI scheme as the solution of problem (18)-(20) made in [2], as it is rather lengthy, and is not essential for our analysis.

The PSI scheme is now cast as a non-linear Petrov-Galerkin scheme with the structure (8) or (9), following the derivation of the first part of this Section. We next prove that it satisfies Hypothesis 2 as follows:

**Lemma 4.2** Assume that all angles between sides (when \( d = 2 \)) or that all dihedral angles between faces (when \( d = 3 \)) of all elements of the grid are of, at most, \( \pi/2 \) degrees.

Then the PSI scheme satisfies Hypothesis 2 for any \( \nu > 0 \).

**Proof:** Under the above hypotheses, the discrete Laplace matrix \( L \) is a M-matrix (Cf., for instance, [15]).

To prove that the discrete advection-diffusion matrix \( A^* = C^* + \nu L \) associated to the PSI method is an M-matrix for any \( \nu > 0 \) for some \( \nu \in \mathbb{V} \), it is enough to prove that the associated discrete advection matrix \( C^* \) verifies (10), (11) and (12) but with non-strict inequalities.

By (18), the elementary coefficients of \( C^* \) on a triangle \( T \) of \( T_h \) are obtained from those of the N scheme \( c_{ij} \) by

\[
(C^*_{ij})^* = -(1 - \mu^T_i) c_{ij}, \quad \text{if} \quad i \neq j, \quad (C^*_{ii})^* = (1 - \mu^T_i) c_{ii}.
\]

As \( c_{ij} \geq 0 \) and \( 0 \leq \mu^T_i \leq 1 \) the conclusion follows. \( \square \)

**Remark 4.1** It does not seem clear that the discrete convection matrix \( C^*(s_h) \) also is positive-defined. The global diagonal element for the PSI scheme is given by

\[
C^*_{kk} = \sum_{T \in E_k} (C^*_{kk})^* = \sum_{T \in E_k} (1 - \mu^T_k) c_{kk} = \sum_{T \in E_k, K^T_T \leq 0} (1 - \mu^T_k) c_{kk} + \sum_{T \in E_k, K^T_T > 0} (1 - \mu^T_k) c_{kk}.
\]

If \( b_k \) is an upstream node for an element \( T \) (i.e., if \( K^T_T = \frac{1}{2} \hat{u}^T \cdot n_k^T \leq 0 \)), then \( c_{kk}^T = \beta_k^T K_k^T = 0 \), and so

\[
C^*_{kk} = \sum_{T \in E_k, K^T_T > 0} (1 - \mu^T_k) c_{kk}.
\]

Given a triangle \( T \in E_k \), denote by \( \Gamma_k \) the side or face of \( \partial T \) opposite to the node \( b_k \), and by \( n_k^T \) the unit normal to \( \partial T \) on \( \Gamma_k \), outward to \( T \). Using the vector function \( \sigma(x) = x - b_k \) we deduce the relation

\[
n_k^T = -\eta_k^T |\Gamma_k|,
\]

where \( n_k^T \) is the inward normal defined in (16).

As \( \nabla \cdot u = 0 \), then

\[
0 = \int \bigcup_{T \in E_k} u \cdot \eta |\Gamma_k| = \sum_{T \in E_k} \int_{\Gamma_k} u \cdot \eta_k^T = \sum_{T \in E_k} \hat{u}^T \cdot n_k^T = d \sum_{T \in E_k} \hat{K}_k^T.
\]
where \( \hat{u}^T = \frac{1}{|\Gamma_k|} \int_{\Gamma_k} u \), and \( \hat{K}_k^T = \frac{1}{d} \hat{u}^T \cdot \eta_k^T \).

Then (excepting very particular grids that can be avoided), for some \( T \in E_k \) we have \( \hat{K}_k^T > 0 \). If \( u \) is smooth and \( h \) is small enough, this implies \( K_k^T > 0 \), and then \( c_{kk}^T > 0 \).

However, we could have \( \hat{\mu}_T = 1 \) if all the flux is sent to node \( i \). This occurs with PSI scheme in the case of "two target triangle" (or three if \( d = 3 \)), as it sends all the flow to one of the targeted vertex (See Figures 2 and 3).

Therefore, we could have \( \hat{C}_{kk}^* = 0 \) if the node \( b_k \) is downstream just for one triangle of \( E_k \), for which it is the target of a two or more target element.

We also have:

**Lemma 4.3** The PSI scheme satisfies Hypothesis 3

**Proof:** The construction of [2] of PSI method yields continuous elementary coefficients \( \hat{\mu}_i^T \) as functions of the fluxes \( \Phi_i^T \). As these are continuous functions of \( s_h \) by (17), we conclude that Hypothesis 3 holds.

\[ \square \]

**Remark 4.2** The construction of [2] allows to build a scheme satisfying properties (18), (19) and (20) from any first-order monotone scheme, and not only from the \( N \) scheme.
In particular, in [2] there are reported the L-Rusanov and the L-upwind, respectively constructed from the Rusanov and the one-dimensional upwind schemes. Thus, the same proofs above prove that these schemes also satisfy Hypotheses 1, 2 and 3.

Consequently, all results of our analysis also apply to the the L-Rusanov and the L-upwind schemes and to any other that could be built by Abgrall and Mezine’s technique from a first-order scheme.

5 Tools

Our analysis is based upon some functional properties of the Distribution Interpolation operator and the discrete advection-diffusion operator appearing in our Petrov-Galerkin methods (8) and (9), that we state in this Section. These properties are deduced from Hypotheses 1 and 2 stated above.

We denote by \( \| \cdot \|_p \) the \( L^p(\Omega) \) norm.

**Lemma 5.1** There exists a constant \( C_p > 0 \) such that
\[
\| \Pi_{r_h} v_h \|_p \leq C_p \| v_h \|_p \quad \forall r_h v_h \in V_h, \forall 1 \leq p < +\infty.
\]

**Proof:**

For simplicity of notation, we drop the subindex \( h \) of \( v_h \).

**Step 1.** Consider a function \( v \in V_h \). By definition, we have:
\[
\| \Pi_{r_h} v \|_p^p = \int_{\Omega} \left| \sum_{i=1}^{N} v(b_i) \lambda_i \right|^p = \sum_{T \in T_h} \int_T \left| \sum_{i=1}^{d+1} v(b_{i_T}) \lambda_{i_T}^T \right|^p,
\]
where \( \lambda_i = \lambda_i(r_h) \). We may write the norm in \( L^p(\Omega) \) of \( v \) as:
\[
\| v \|_p^p = \sum_{T \in T_h} \int_T \left| \sum_{i=1}^{d+1} v(b_{i_T}) B_i(x) \right|^p dx,
\]
where \( B_i(x) \), \( 1 \leq i \leq d+1 \) are the baricentric coordinates of \( x \) in the element \( T \).

First, we are going to prove that there exists a constant \( C_p^* \) such that:
\[
\left( \int_T \sum_{i=1}^{d+1} |v(b_{i_T})|^p dx \right)^{1/p} \leq C_p^* \left( \int_T \left| \sum_{i=1}^{d+1} v(b_{i_T}) B_i(x) \right|^p dx \right)^{1/p}.
\]

To see it, consider a change of variables from the reference element \( \hat{T} \) into \( T \). If we take \( \hat{x} \in \hat{T} \), we define \( x \in T \) such that \( x = A_T \hat{x} + b_T \), then \( dx = | \det A_T | d\hat{x} \).

Furthermore, we can write \( |T| = \int_T dx = | \det A_T | |\hat{T}| \), so \( | \det A_T | = \frac{|T|}{|\hat{T}|} \).
Define the seminorms $| \cdot |_1$ and $| \cdot |_2$ on the space $C^0(T)$ as follows:

$$ |v|_1 = \left( \int_T \left| \sum_{i=1}^{d+1} v(b_{i_T}) B_i(x) \right|^p dx \right)^{1/p}; $$

$$ |v|_2 = \left( \int_T \left| \sum_{i=1}^{d+1} |v(b_{i_T})|^p dx \right| \right)^{1/p} = |T|^{1/p} \left( \int_T \left| \sum_{i=1}^{d+1} |v(b_{i_T})|^p \right| \right)^{1/p}. $$

If we apply the change of variables in the definition of $|v|_1$ we have:

$$ |v|_1 = \left( \int_T |\det A_T| \left| \sum_{i=1}^{d+1} v(b_{i_T}) \hat{B}_i(\hat{x}) \right|^p d\hat{x} \right)^{1/p} = \frac{|T|^{1/p}}{|T|^{1/p}} \left( \int_T \left| \sum_{i=1}^{d+1} v(b_{i_T}) \hat{B}_i(\hat{x}) \right|^p d\hat{x} \right)^{1/p}. $$

We next define two norms on $\mathbb{R}^{d+1}$. Given $z = (z_1, \ldots, z_{d+1}) \in \mathbb{R}^{d+1}$ we define:

$$ |z|_1 = \frac{1}{|T|^{1/p}} \left( \int_T \left| \sum_{i=1}^{d+1} z_i \hat{B}_i(\hat{x}) \right|^p d\hat{x} \right)^{1/p}; $$

$$ |z|_2 = \left( \sum_{i=1}^{d+1} |z_i|^p \right)^{1/p}. $$

As we have a finite dimensional space, the norms are equivalent, so there exists a constant $C^*_p$ such that

$$ |z|_2^* \leq C^*_p |z|_1^*, \quad \forall z \in \mathbb{R}^{d+1}. $$

If we consider now $v_T = (v(b_{1_T}), \ldots, v(b_{(d+1)_T}))'$ as a vector of $\mathbb{R}^{d+1}$, and we use the definitions of $|v_T|_1$ and $|v_T|_2$, we deduce (21).

**Step 2.** Let us conclude that $\|\Pi_h v\|_p \leq C^*_p \|v\|_p$.

$$ \|\Pi_h v\|_p^p = \sum_{T \in T_h} \int_T \left| \sum_{i=1}^{d+1} v(b_{i_T}) \chi_{i_T}^T \right|^p \leq \sum_{T \in T_h} \int_T \left| \sum_{i=1}^{d+1} v(b_{i_T}) \chi_{i_T}^T \right|^p. $$

But by Hypothesis 1, we have $\lambda_{i_T}^T \geq 0, \forall 1 \leq i \leq d+1$ and $\sum_{i=1}^{d+1} \lambda_{i_T}^T = 1$. As the function $g(x) = x^p$ with $p \geq 1$ is convex, then

$$ \|\Pi_h v\|_p^p \leq \sum_{T \in T_h} \int_T \sum_{i=1}^{d+1} |v(b_{i_T})|^p \lambda_{i_T}^T \leq \sum_{T \in T_h} \int_T \sum_{i=1}^{d+1} |v(b_{i_T})|^p, $$

because each $\lambda_{i_T}^T \leq 1$. 

13
Thus $\|\Pi_r h v\|_p^p \leq \sum_{T \in T_h} |v_T|^p$ and using (21):

$$\|\Pi_r h v\|_p^p \leq \left( C^*_p \right)^p \sum_{T \in T_h} |v_T|^p = \left( C^*_p \right)^p \sum_{T \in T_h} \int_T \sum_{i=1}^{d+1} v(b_{iT}) B_i(x) \bigg| \sum_{i=1}^{d+1} v(b_{iT}) B_i(x) \bigg|^p dx = \left( C^*_p \right)^p \|v\|_p^p.$$ 

This yields the conclusion.

$\square$

**Lemma 5.2** Consider a function $\sigma_h \in V_h$. Then,

$$\|\Pi_r h \sigma_h - \sigma_h\|_p \leq h \|\nabla \sigma_h\|_p \quad \forall p \in [1, +\infty], \quad \forall r_h \in V_h.$$ 

**Proof:**

By the definition of $\Pi_r h$ and Hypothesis 1,

$$\|\Pi_r h \sigma_h - \sigma_h\|_p^p = \sum_{T \in T_h} \int_T |(\Pi_r h \sigma_h)(x) - \sigma_h(x)|^p dx =$$

$$\sum_{T \in T_h} \int_T \left| \sum_{i=1}^{d+1} \sigma_h(b_{iT}) \lambda_{iT}^T - \sum_{i=1}^{d+1} \sigma_h(x) \lambda_{iT}^T \right|^p dx.$$ 

Using the convexity of function $g(x) = x^p$ for $p \geq 1$,

$$\|\Pi_r h \sigma_h - \sigma_h\|_p^p \leq \sum_{T \in T_h} \int_T \left[ \sum_{i=1}^{d+1} \lambda_{iT}^T |\sigma_h(b_{iT}) - \sigma_h(x)| \right]^p dx \leq$$

$$\sum_{T \in T_h} \int_T \sum_{i=1}^{d+1} \lambda_{iT}^T |\sigma_h(b_{iT}) - \sigma_h(x)|^p dx.$$ 

As $\sigma_h$ is linear, $\sigma_h(b_{iT}) - \sigma_h(x) = \nabla \sigma_h_{iT} \cdot (b_{iT} - x)$. So,

$$|\sigma_h(b_{iT}) - \sigma_h(x)| \leq |\nabla \sigma_h_{iT}| h_T,$$

where $h_T$ is the diameter of the element $T$. Thus, by Hypothesis 1,

$$\|\Pi_r h \sigma_h - \sigma_h\|_p^p \leq \sum_{T \in T_h} \int_T \sum_{i=1}^{d+1} \lambda_{iT}^T h_T^p |\nabla \sigma_h_{iT}|^p dx \leq h_T^p \sum_{T \in T_h} \int_T |\nabla \sigma_h_{iT}|^p dx \leq h_T^p \|\nabla \sigma_h\|_{L^p(\Omega)}^p.$$ 

If $p = +\infty$, the result also follows from (22).
Note that this result gives an error estimate for the distribution interpolation of piecewise affine finite elements. This estimate will be crucial to handle the transport and up-winded source terms in our error analysis.

We next give a technical lemma to handle the convergence of our discrete approximations (8) and (9).

We shall denote
\[ \|v\|_V = \|\nabla v\|_2, \quad \forall v \in V. \]

This is a norm on \( V \) equivalent to the \( H^1(\Omega) \) norm.

**Lemma 5.3** Assume that the family of triangulations \( \{T_h\}_{h>0} \) is regular. Then the following holds

a) Given \( v \in V \), for any sequence \( \{r_h\}_{h>0} \subset V \) with \( r_h \in V_h \), \( \forall h > 0 \), there exists a sequence \( \{v_h\}_{h>0} \subset V \) such that \( v_h \in V_h \), \( \forall h > 0 \), satisfying
\[
\lim_{h \to 0} \|\Pi_{r_h} v_h - v\|_r = 0, \quad \text{for any } r \in [1, r_{max}),
\]
where \( r_{max} = +\infty \) if \( d = 2 \) and \( r_{max} = 6 \) if \( d = 3 \).

b) Given \( v \in V \) consider a sequence \( \{v_h\}_{h>0} \subset V \) with \( v_h \in V_h \), \( \forall h > 0 \), that verifies
\[
\lim_{h \to 0} \|v_h - v\|_r = 0, \quad \text{for any } r \in [1, r_{max}).
\]

Then,
\[
\lim_{h \to 0} \|\Pi_{r_h} v_h - v\|_r = 0.
\]

**Proof:**

a) As the family of triangulations is regular, there exits a sequence \( \{v_h\}_{h>0} \subset V \) such that \( v_h \in V_h \), \( \forall h > 0 \), strongly convergent to \( v \) in \( V \) (Cf [6]). As \( H^1(\Omega) \) is compactly embedded in \( L^r(\Omega) \) if \( 1 \leq r < r_{max} \), we may assume that this sequence is strongly convergent to \( v \) in \( L^r(\Omega) \). Using Lemma 5.2,
\[
\|\Pi_{r_h} v_h - v\|_r \leq \|\Pi_{r_h} v_h - v_h\|_r + \|v_h - v\|_r \leq h \|\nabla v_h\|_r + \|v_h - v\|_r
\]

For \( 1 \leq r \leq 2 \),
\[
\|\nabla v_h\|_r \leq \|\nabla v_h\|_2.
\]

For \( r \in (2, +\infty) \), we use an inverse inequality for finite elements (See [7], for instance): Because of the regularity of the mesh, there exists a constant \( C_1 > 0 \) such that:
\[
\|\nabla v_h\|_r \leq C_1 h^{d(\frac{1}{2} - \frac{1}{r})} \|\nabla v_h\|_2 \quad \forall r > 2, \quad \forall v_h \in V_h.
\]
Then,
\[ \| \Pi_{\mathbf{r}} \mathbf{v}_h - \mathbf{v} \|_r \leq C_1 h^\beta \| \nabla \mathbf{v}_h \|_2 + \| \mathbf{v}_h - \mathbf{v} \|_r \]
with \( \beta = 1 - d(1/2 - 1/r) > 0 \) if \( r \in (2, r_{\text{max}}) \) and \( \beta = 1 \) if \( r \in [1, 2] \). This proves a)

b) Consider \( \mathbf{v} \in \mathcal{V} \). Again, there exists a sequence \( \{ \mathbf{z}_h \}_{h>0} \subset \mathcal{V} \) such that \( \mathbf{z}_h \in \mathcal{V}_h \), \( \forall h > 0 \), strongly convergent to \( \mathbf{v} \) in \( \mathcal{V} \cap L^r(\Omega) \). Using Lemmas 5.1 and 5.2,
\[ \| \Pi_{\mathbf{r}} \mathbf{v}_h - \mathbf{v}_h \|_r \leq \| \Pi_{\mathbf{r}} \mathbf{v}_h - \Pi_{\mathbf{r}} \mathbf{z}_h \|_r + \| \Pi_{\mathbf{r}} \mathbf{z}_h - \mathbf{z}_h \|_r + \| \mathbf{z}_h - \mathbf{v} \|_r \leq \]
\[ \leq C_p \| \mathbf{v}_h - \mathbf{z}_h \|_r + h \| \nabla \mathbf{z}_h \|_r + \| \mathbf{z}_h - \mathbf{v} \|_r \]
\[ \leq C_p \| \mathbf{v}_h - \mathbf{v} \|_r + (C_p + 1) \| \mathbf{z}_h - \mathbf{v} \|_r + h \| \nabla \mathbf{z}_h \|_r . \]

Proceeding as in the proof of a),
\[ h \| \nabla \mathbf{z}_h \|_r \leq C_1 h^\beta \| \nabla \mathbf{z}_h \|_0 . \]
with the same values for \( \beta \). Then, b) follows.

**Lemma 5.4** Under Hypothesis 1, for any \( \mathbf{r}_h \in \mathcal{V}_h \), the form \( b(\mathbf{r}_h) : \mathcal{V}_h \times \mathcal{V}_h \to \mathbb{R} \) defined by
\[ b(\mathbf{r}_h; \mathbf{v}_h, \mathbf{w}_h) = \int_{\Omega} (\mathbf{u} \cdot \nabla \mathbf{v}_h) \Pi_{\mathbf{r}_h} \mathbf{w}_h \]
is bilinear and bounded, satisfying
\[ b(\mathbf{r}_h; \mathbf{v}_h, \mathbf{w}_h) \leq C_q \| \mathbf{u} \|_q \| \mathbf{v}_h \|_{\mathcal{V}} \| \mathbf{w}_h \|_{\mathcal{V}} , \]
where \( C_q \) is a positive constant.

**Proof:** This is a direct consequence of Lemma 5.1 and the Sobolev embedding of \( H^1(\Omega) \) in \( L^r(\Omega) \), if \( 1 \leq r \leq r_{\text{max}} \) (excluding the case \( r = +\infty \)).

Note that all the above properties of operator \( \Pi_{\mathbf{r}_h} \) rely only on Hypothesis 1. We next state some properties of the discrete advection operator, that shall also rely on Hypothesis 2.

**Lemma 5.5** Under Hypotheses 2, for any \( \mathbf{r}_h \in \mathcal{V}_h \), the form \( b(\mathbf{r}_h) \) is semi-positive, in the sense that it satisfies
\[ b(\mathbf{r}_h; \mathbf{v}_h, \mathbf{v}_h) \geq 0 \quad \forall \mathbf{v}_h \in \mathcal{V}_h . \]
Proof: Consider an element \( z_h = \sum_{i=1}^{M} z_i \varphi_i \in V_h \). Then,

\[
b(r_h; z_h, z_h) = \int_{\Omega} (u \cdot \nabla z_h) \Pi r_h z_h = \sum_{i,j=1}^{M} \int_{\Omega} (u \cdot \nabla \varphi_j) \Pi r_h \varphi_i z_i z_j =
\]

\[
= \sum_{i,j=1}^{M} z_i C_{i,j}(r_h) z_j = Z^t C(r_h) Z,
\]

where \( Z = (z_1 \ldots z_M)^t \). Then,

\[
\int_{\Omega} (u \cdot \nabla z_h) \Pi r_h z_h + \nu \int_{\Omega} \nabla z_h \cdot \nabla z_h = Z^t (C(r_h) + \nu L) Z = Z^t A_{\nu}(r_h) Z.
\]

By Hypothesis 2 \( A_{\nu}(r_h) \) is a M-matrix, then it is semi-positive defined, and

\[
b(r_h; z_h, z_h) = \lim_{\nu \to 0^+} Z^t A_{\nu}(r_h) Z \geq 0.
\]

Note that this result proves that Hypothesis 2 could alternatively be formulated as

Hypothesis 2’

Matrix \( C(s_h) \) is semi-positive defined for any \( s_h \in V_h \), and matrix \( L \) is an M-matrix.

It is doubtful that matrix \( L \) is positive defined for PSI scheme (See Remark 4.1).

6 Existence and quasi-uniqueness

In this section we prove the existence of solution for the discrete problems (8) and (9). Also, we obtain an estimate for the difference between two solutions of the same problem. The proof of uniqueness is an open question due to the non-linear nature of the method we are considering.

To prove the existence of solution for the problem above, we shall use a particular form of Brouwer’s Fixed Point Theorem that we state in the Lemma 6.1 (cf. [17, 31]). The semi-positiveness of the discrete convective operator (Lemma 5.5) plays a crucial role in this proof.

Lemma 6.1 Let \( X \) be a finite dimensional Hilbert space with scalar product \( \langle \cdot , \cdot \rangle \) and norm \( [\cdot ] \). Let \( P \) be a continuous mapping from \( X \) into itself such that:

\[
[P(\xi_0), \xi_0] > 0 \quad \text{for} \quad [\xi_0] = k > 0.
\]

Then \( \exists \xi \in X \), with \( [\xi] \leq k \), such that

\[
P(\xi) = 0.
\]
The existence of solutions of Problem (9) is stated by

**Theorem 6.1** Assume that \( u \in (L^q(\Omega))^d \) for some \( q > d \), \( f \in L^p(\Omega) \) for \( p > 1 \) if \( d = 2 \) and \( p > 6/5 \) if \( d = 3 \). Then problem (9) admits at least one solution \( \rho_h \in V_h \) that satisfies the estimate

\[
\| \rho_h \|_V \leq \frac{C}{\nu} \| f \|_p
\]

(26)

where the constant \( C > 0 \) only depends on \( d, p \) and \( \Omega \).

**Proof:**

We define the mapping \( P : V_h \rightarrow V_h \) as follows

\[
[P(v_h), w_h] = b(v_h; v_h, w_h) + \nu(\nabla v_h; \nabla w_h) - (f, \Pi v_h w_h), \quad \forall v_h, w_h \in V_h.
\]

Due to Hypothesis 3, \( P \) is a continuous mapping on \( V_h \). Also,

\[
[P(v_h), v_h] = b(v_h; v_h, v_h) + \nu\|\nabla v_h\|_2^2 - (f, \Pi v_h v_h).
\]

Using Lemma 5.1 and the Sobolev embedding of \( H^1(\Omega) \) in \( L^r(\Omega) \), we obtain

\[
|(f, \Pi v_h v_h)| \leq C_{p'} \| f \|_p \| v_h \|_{p'} \leq C_{p'} C \| f \|_p \| \nabla v_h \|_2
\]

As \( b(v_h) \) is positive, we may write:

\[
[P(v_h), v_h] \geq \nu\|\nabla v_h\|_2^2 - C \| f \|_p \| \nabla v_h \|_2 = \| \nabla v_h \|_2 (\nu \| \nabla v_h \|_2 - C \| f \|_p).
\]

Then, for \( \| \nabla v_h \|_2 = k \), \( [P(v_h), v_h] > 0 \), for \( k > \frac{C \| f \|_p}{\nu} \). Therefore, by Lemma 6.1, \( \exists \rho_h \in V_h \) such that \( P(\rho_h) = 0 \). Then \( \rho_h \) is a solution of (9).

Furthermore,

\[
0 = [P(\rho_h), \rho_h] \geq \| \nabla \rho_h \|_2 (\nu \| \nabla \rho_h \|_2 - \| f \|_p).
\]

So (26) holds. \( \square \)

Also, the existence of solution of Problem (8) is stated as

**Theorem 6.2** Assume that \( u \in (L^q(\Omega))^d \) for some \( q > d \), \( f \in V' \). Then problem (8) admits at least one solution \( \rho_h \in V_h \) that satisfies the estimate

\[
\| \rho_h \|_V \leq \frac{1}{\nu} \| f \|_{V'}.
\]

(27)

**Proof:** Proceeding as in the proof of Theorem 6.1, we can write

\[
[P(v_h), v_h] \geq \nu\|\nabla v_h\|_2^2 - \| f \|_{V'} \| \nabla v_h \|_2 = \| \nabla v_h \|_2 (\nu \| \nabla v_h \|_2 - \| f \|_{V'}).
\]

By Lemma 6.1, \( \exists \rho_h \in V_h \) such that \( P(\rho_h) = 0 \). Then \( \rho_h \) is solution of (8) and so (27) holds.
The proximity between two possible solutions of problem (9) is stated in the following result.

**Lemma 6.2** Assume that the family of triangulations \( \{T_h\}_{h>0} \) is regular. Assume that \( f \in L^p(\Omega) \) for some \( p > 1 \). Let \( \rho_{1h} \) and \( \rho_{2h} \) be two solutions of problem (9). Then there exists a constant \( C > 0 \) such that

\[
\| \nabla (\rho_{1h} - \rho_{2h}) \|_2 \leq \frac{C}{\nu^2} \| u \|_q \| f \|_p h^\alpha + \frac{C}{\nu} \| f \|_p h^\beta,
\]

where \( \alpha = 1 - \frac{d}{q} \) and \( \beta = \begin{cases} 1 & \text{if } 2 \leq p < +\infty, \\ 1 + d \left( \frac{1}{2} - \frac{1}{p} \right) & \text{if } 1 < p < 2 \text{ for } d = 2, \\ 6/5 & \text{if } 6/5 < p < 2 \text{ for } d = 3. \end{cases} \)

**PROOF:**

Using the previous notation, we can write

\[
0 = [P(\rho_{1h}) - P(\rho_{2h}), w_h] = [b(\rho_{1h}; \rho_{1h}, w_h) - (u \cdot \nabla \rho_{1h}, w_h)] + \\
+ [((u \cdot \nabla \rho_{1h}, w_h) - (u \cdot \nabla \rho_{2h}, w_h)) + [(u \cdot \nabla \rho_{2h}, w_h) - b(\rho_{2h}; \rho_{2h}, w_h)] + \\
+ \nu(\nabla (\rho_{1h} - \rho_{2h}), \nabla w_h) + (f, \Pi_{\rho_{2h}} w_h - \Pi_{\rho_{1h}} w_h). \tag{28}
\]

By definition of \( b \),

\[
|b(\rho_{1h}; \rho_{1h}, w_h) - (u \cdot \nabla \rho_{1h}, w_h)| = |(u \cdot \nabla \rho_{1h}, \Pi_{\rho_{1h}} w_h - w_h)| \leq \|u\|_q \| \nabla \rho_{1h}\|_2 \| \Pi_{\rho_{1h}} w_h - w_h\|_q \leq h \|u\|_q \| \nabla \rho_{1h}\|_2 \| \nabla w_h\|_q,
\]

with \( \frac{1}{q} + \frac{1}{q} = \frac{1}{2} \), where we have used Lemma 5.2 in the last estimate. We next use the inverse inequality (25) that yields

\[
\| \nabla w_h\|_q \leq C_1 h^{d(\frac{1}{2} - \frac{1}{q})} \| \nabla w_h\|_2.
\]

So we have

\[
|b(\rho_{1h}; \rho_{1h}, w_h) - (u \cdot \nabla \rho_{1h}, w_h)| \leq \frac{C_2}{\nu} h^{1 - \frac{d}{q}} \|u\|_q \|f\|_p \| \nabla w_h\|_2,
\]

where we have used estimate (26).

By another hand, if \( w_h = \rho_{1h} - \rho_{2h} \), the second summand in the r.h.s. of (28) is

\[
(u \cdot \nabla (\rho_{1h} - \rho_{2h}), \rho_{1h} - \rho_{2h}) = \frac{1}{2} \int_{\Gamma^+} u \cdot n (\rho_{1h} - \rho_{2h})^2 d\sigma \geq 0.
\]

We now estimate the last summand of (28)

\[
|(f, \Pi_{\rho_{2h}} w_h - \Pi_{\rho_{2h}} w_h)| \leq \|f\|_p \|\Pi_{\rho_{2h}} w_h - w_h\|_{p'} + \|f\|_p \|\Pi_{\rho_{1h}} w_h - w_h\|_{p'} \leq 2C_3 h \|f\|_p \| \nabla w_h\|_{p'}
\]

19
where we use Lemma 5.2.

If \( p \geq 2 \) then \( \|\nabla w_h\|_{p'} \leq \|\nabla w_h\|_2 \) and if \( p < 2 \), we can use the inverse estimate (25). So,

\[
|\langle f, \Pi_{p_{2h}} w_h - \Pi_{p_{2h}} w_h \rangle| \leq 2C_3 h^{\beta} \|f\|_p \|\nabla w_h\|_2
\]  

(29)

with \( \beta = \begin{cases} 1 & \text{if } 2 \leq p < +\infty, \\ 1 + \frac{d}{2} - \frac{1}{2} & \text{if } p < 2. \end{cases} \)

Thus, setting \( w_h = \rho_{1h} - \rho_{2h} \), we have from (28),

\[
\nu \|\nabla (\rho_{1h} - \rho_{2h})\|_2^2 \leq 2C_2 \nu h^{1-\frac{d}{q}} \|u\|_q \|f\|_p \|\nabla (\rho_{1h} - \rho_{2h})\|_2 + 2C h^{\beta} \|f\|_p \|\nabla (\rho_{1h} - \rho_{2h})\|_2,
\]

that yields the result.

\[ \square \]

In the same way, we can prove the following result for problem (8)

**Lemma 6.3** Assume that the family of triangulations \( \{T_h\}_{h>0} \) is regular. Let \( \rho_{1h} \) and \( \rho_{2h} \) be two solutions of problem (8). Then there exists a constant \( C > 0 \) such that

\[
\|\nabla (\rho_{1h} - \rho_{2h})\|_2 \leq \frac{C}{\nu^{1-\frac{d}{q}}} \|u\|_q \|f\|_p
\]

7 Convergence analysis and error estimates

We next prove the strong convergence in \( H^1 \)-norm of a solution of the discretizations (8) and (9) to the solution of the continuous problem (1) and error estimates in \( H^1 \)-norm. We prove the result for discretization (9), as this is the more involved technically, and just state it for discretization (8).

**Theorem 7.1** Let \( \Omega \) be a bounded polygonal domain of \( \mathbb{R}^d \). Assume that the family of triangulations \( \{T_h\}_{h>0} \) is regular. Assume that data of the advection-diffusion problem (1) verify \( u \in (L^q(\Omega))^d \) for some \( q > d \), \( f \in L^p(\Omega) \) for \( p > 1 \) if \( d = 2 \) and \( p > 6/5 \) if \( d = 3 \).

Then the sequence of solutions \( \{\rho_{h}\}_{h>0} \) of the discretization (9) is strongly convergent in \( V \) to the solution \( \rho \) of problem (1) as \( h \) goes to zero.

**Proof:** a) By (26), the sequence \( \{\rho_{h}\}_{h>0} \) is bounded in \( V \). This is a closed sub-space of \( H^1(\Omega) \). Then there exists a subsequence \( \{\rho_{h'}\}_{h'>0} \) weakly convergent in \( V \) to some \( \rho^* \).

Consider \( v \in V \), by Lemma 5.3 there exists a sequence \( \{v_{h}\}_{h>0} \subset V \) such that \( v_{h} \in V_{h}, \forall h > 0 \), satisfying

\[
\lim_{h \to 0} \|\Pi_{p_{h}} v_{h} - v\|_r = 0, \quad r \in [1, r_{max})
\]

20
If \( u \in (L^q(\Omega))^d \) with \( q > d \), \( \hat{q} \in [1, r_{\max}) \) where \( \hat{q} \) is such that \( \frac{1}{q} + \frac{1}{\hat{q}} = \frac{1}{2} \). Then,
\[
\lim_{h' \to 0} \int_{\Omega} (u \cdot \nabla \rho_h') \Pi_{\rho_h'} v_h = \int_{\Omega} (u \cdot \nabla \rho^*) \cdot v;
\]

Also, as \( f \in L^p(\Omega) \) with \( p > 1 \) if \( d = 2 \) and \( p > 6/5 \) if \( d = 3 \), then \( p' \in [1, r_{\max}) \) and so,
\[
\lim_{h' \to 0} \int_{\Omega} f \Pi_{\rho_h'} v_h = \int_{\Omega} f v.
\]

Consequently, \( \rho^* \) satisfies
\[
\int_{\Omega} (u \cdot \nabla \rho^*) \cdot v + \nu \int_{\Omega} \nabla \rho^* \cdot \nabla v = \int_{\Omega} f v, \quad \forall v \in V.
\]

We deduce that \( \rho^* \) is the weak solution of problem (1), that we have denoted \( \rho \). As this solution is unique, the whole sequence \( \{\rho_h\}_{h>0} \) converges weakly to \( \rho \) in \( V \).

b) We prove the convergence of the \( H^1(\Omega) \) semi-norm of \( \rho_h \) to the \( H^1(\Omega) \) semi-norm of \( \rho \). This proves the strong convergence as this is a norm on \( V \) equivalent to the norm of \( H^1(\Omega) \). We follow the standard procedure. Respectively take \( v = \rho \) and \( v_h = \rho_h \) as test functions in the continuous and discrete problems (2) and (9). Then we have
\[
\int_{\Omega} (u \cdot \nabla \rho) \cdot v + \nu \int_{\Omega} |\nabla \rho|^2 = \int_{\Omega} f \rho; \quad (30)
\]

and
\[
\int_{\Omega} (u \cdot \nabla \rho_h) \Pi_{\rho_h} \rho_h + \nu \int_{\Omega} |\nabla \rho_h|^2 = \int_{\Omega} f \Pi_{\rho_h} \rho_h; \quad (31)
\]

By Lemma 5.3 b), \( \Pi_{\rho_h} \rho_h \) strongly converges to \( \rho \) in \( L^2(\Omega) \). Then,
\[
\lim_{h \to 0} \int_{\Omega} (u \cdot \nabla \rho_h) \Pi_{\rho_h} \rho_h = \int_{\Omega} (u \cdot \nabla \rho) \rho.
\]

Also, as \( f \) belongs to \( L^p(\Omega) \),
\[
\lim_{h \to 0} \int_{\Omega} f \Pi_{\rho_h} \rho_h = \int_{\Omega} f \rho.
\]

So we may pass to the limit in (31) to deduce using (30) that
\[
\lim_{h \to 0} \int_{\Omega} |\nabla \rho_h|^2 = \int_{\Omega} |\nabla \rho|^2.
\]

This concludes the proof.
The convergence of approximation (8) requires less regularity for the source term. It is stated as follows.

**Theorem 7.2** Let \( \Omega \) be a bounded polygonal domain of \( \mathbb{R}^d \). Assume that the family of triangulations \( \{T_h\}_{h>0} \) is regular. Assume that the data of the advection-diffusion problem (1) verify \( u \in (L^q(\Omega))^d \) for some \( q > d \), \( f \in V' \).

Then the sequence of solutions \( \{\rho_h\}_{h>0} \) of the discretization (8) is strongly convergent in \( V \) to the solution \( \rho \) of problem (1) as \( h \) goes to zero.

We next state our main error estimates result.

**Theorem 7.3** Under the hypotheses of Theorem 7.1, the following error estimates for the solutions of the discrete problems (9) hold:

\[
\|\nabla (\rho - \rho_h)\|_2 \leq (2 + \frac{C}{\nu}) \|u\|_q d_1(\rho, V_h) + \frac{C}{\nu^2} \|u\|_q \|f\|_p h^\alpha + \frac{C}{\nu} \|f\|_p h^\beta,
\]

where \( d_1(\rho, V_h) = \inf_{v_h \in V_h} \|\nabla (\rho - v_h)\|_2 \), \( C > 0 \) is a constant independent of \( h \) and \( \nu \),

\[
\alpha = 1 - \frac{d}{q} > 0, \quad \beta = \begin{cases} 1 & \text{if } 2 \leq p < +\infty \\ 1 + d \left( \frac{1}{2} - \frac{1}{p} \right) & \text{if } 1 < p < 2 \text{ for } d = 2 \\ & \text{if } 6/5 < p < 2 \text{ for } d = 3. \end{cases}
\]

**Proof:**

Denote by \( P_h \) the elliptic projection of \( \rho \) onto \( V_h \) and define the truncation error \( \epsilon_h \in V' \) as:

\[
< \epsilon_h, v > = (u \cdot \nabla P_h, v) + \nu(\nabla P_h, \nabla v) - (f, v) \quad \forall \ v \in V.
\]

Take \( v = v_h \in V_h \) in this expression and substitute it to (9):

\[
(u \cdot \nabla \rho_h, \Pi_{\rho h} v_h) + \nu(\nabla \rho_h, \nabla v_h) - (u \cdot \nabla P_h, v_h) - \nu(\nabla P_h, \nabla v_h) - (f, \Pi_{\rho h} v_h - v_h) = < \epsilon_h, v_h >.
\]

**Interpolation error estimate.**

Define the interpolation error as \( \epsilon_h = \rho_h - P_h \in V_h \). Then:

\[
(u \cdot \nabla \rho_h, \Pi_{\rho h} v_h) - (u \cdot \nabla P_h, v_h) + \nu(\nabla \epsilon_h, \nabla v_h) - (f, \Pi_{\rho h} v_h - v_h) = < \epsilon_h, v_h >.
\]

Summing and subtracting \( (u \cdot \nabla P_h, \Pi_{\rho h} v_h) \) in the left-hand side,

\[
(u \cdot \nabla \epsilon_h, \Pi_{\rho h} v_h) + (u \cdot \nabla P_h, \Pi_{\rho h} v_h - v_h) + \nu(\nabla \epsilon_h, \nabla v_h) - (f, \Pi_{\rho h} v_h - v_h) = < \epsilon_h, v_h >.
\]

Taking \( v_h = e_h \),

\[
(u \cdot \nabla \epsilon_h, \Pi_{\rho h} e_h) + (u \cdot \nabla P_h, \Pi_{\rho h} e_h - e_h) + \nu \|\nabla \epsilon_h\|^2 - (f, \Pi_{\rho h} e_h - e_h) = < \epsilon_h, e_h >.
\]

22
Thus, thanks to the semi-positiveness of the scheme,
\[
\nu \| \nabla e_h \|_2^2 \leq -\langle \epsilon_h, e_h \rangle - (u \cdot \nabla P_h, \Pi_{\rho_h} e_h - e_h) - (f, \Pi_{\rho_h} e_h - e_h).
\]
\[
\leq -\langle \epsilon_h, e_h \rangle + \| u \|_q \| \nabla P_h \|_2 \| \Pi_{\rho_h} e_h - e_h \|_{\tilde{q}}
\]
+ \| f \|_p \| \Pi_{\rho_h} e_h - e_h \|_{p'},
\]
where \( \frac{1}{q} + \frac{1}{\tilde{q}} = \frac{1}{2}, \frac{1}{p} + \frac{1}{p'} = 1. \)

As \( \tilde{P}_h \) is the orthogonal projection of \( \rho \) on \( V_h \),
\[
\| \nabla \tilde{P}_h \|_2 \leq \| \nabla \rho \|_2 \leq C \nu \| f \|_p.
\]
(35)

By another hand, proceeding as in the obtention of estimate (29) in Lemma 6.2, we have
\[
\| \Pi_{\rho_h} e_h - e_h \|_{\tilde{q}} \leq C h^\alpha \| \nabla e_h \|_2
\]
(36)

with \( \alpha = 1 - \frac{d}{q} \), and
\[
\| \Pi_{\rho_h} e_h - e_h \|_{p'} \leq C h^\beta \| \nabla e_h \|_2
\]
(37)

where \( \beta = \left\{ \begin{array}{ll}
1 & \text{if } 2 \leq p < +\infty, \\
1 + d \left( \frac{1}{2} - \frac{1}{p} \right) & \text{if } 1 < p < 2 \text{ for } d = 2,
\end{array} \right. \)
\[
\left\{ \begin{array}{ll}
1 + d \left( \frac{1}{2} - \frac{1}{p} \right) & \text{if } 6/5 < p < 2 \text{ for } d = 3.
\end{array} \right.
\]

Inserting estimates (35), (36), and (37), into (34) we obtain
\[
\nu \| \nabla e_h \|_2^2 \leq -\langle \epsilon_h, e_h \rangle + C \frac{1}{\nu} \| u \|_q \| f \|_p \| \nabla \tilde{e}_h \|_2 + C h^\beta \| f \|_p \| \nabla e_h \|_2.
\]
Thus,
\[
\nu \| \nabla e_h \|_2 \leq \| \epsilon_h \|_{V'} + C \frac{1}{\nu} \| u \|_q \| f \|_p + C h^\beta \| f \|_p.
\]
(38)

**Truncation error estimate.**

To obtain the estimate for the truncation error, we subtract (2) to (33):
\[
(u \cdot \nabla \rho, v) + \nu (\nabla \rho, \nabla v) - (u \cdot \nabla P_h, v) - \nu (\nabla P_h, \nabla v) = -\langle \epsilon_h, v \rangle.
\]

Thus,
\[
\langle \epsilon_h, v \rangle = (u \cdot \nabla (P_h - \rho), v) + \nu (\nabla (P_h - \rho), \nabla v).
\]
We bound this expression using Sobolev injections. We use that as \( q > d \), then \( \tilde{q} < r_{\text{max}} \):
\[
\langle \epsilon_h, v \rangle \leq (\| u \|_q \| v \|_{\tilde{q}} + \nu \| \nabla v \|_2) \| \nabla (P_h - \rho) \|_2
\]
\[
\leq (C \| u \|_q + \nu) \| \nabla (P_h - \rho) \|_2 \| \nabla v \|_2;
\]
and
\[
\| \epsilon_h \|_{V'} \leq (C \| u \|_q + \nu) d_1(\rho, V_h),
\]
where we have used \( d_1(\rho, V_h) = \| \nabla (P_h - \rho) \|_2. \)

**Conclusion.**

Inserting estimate (39) into (38), we obtain estimate (32).
The obtention of error estimates for Problem (8) may be treated as a sub-case of the preceding analysis. In the case of Problem (8), the error term due to the upwinding of the source term does not appear. We may prove the following error estimate result:

**Theorem 7.4** Under the hypotheses of Theorem 7.2, the following error estimates for the solutions of the discrete problems (8) hold:

\[ \| \nabla (\rho - \rho_h) \|_2 \leq (2 + \frac{C}{\nu}\|u\|_q) d_1(\rho,V_h) + \frac{C}{\nu^2}\|u\|_q\|f\|_{V',V} h^{(1-\frac{d}{2})}, \]  

(40)

**Remark 7.1** The error estimate (32) is of optimal order when \( u \in L^\infty(\Omega) \) and \( f \in L^2(\Omega) \). Indeed, in this case the error term due to the distribution interpolate of the test function is of order \( O(h) \). This is the same order as the interpolation error on \( V_h \), as \( d_1(\rho,V_h) \) is \( O(h) \) if \( \rho \in H^2(\Omega) \). In the case of problem (8), the error estimate (40) is of optimal order when \( u \in L^\infty(\Omega) \).

8 Maximum principle and \( L^r \)-estimates

In this section we prove that the maximum principle is satisfied for the discrete problems, and that we obtain \( L^r \) estimates for the discrete solutions for convex polygonal domains.

We only prove the \( L^r \) estimates for \( d = 3 \) since for \( d = 2 \) are immediate due to Sobolev embeddings.

**Theorem 8.1** Under the conditions of Theorem 6.1 or Theorem 6.2, respectively, assume \( f \geq 0 \). Then, any solution \( \rho_h \) of the discrete problem (9) or (8), respectively, is non-negative.

**Proof:**

We have approximated the advection-diffusion problem by a positive method defined by a matrix \( A_\nu(\rho_h) = C(\rho_h) + \nu L \).

Let us denote by \( R = (\rho(b_1), \cdots, \rho(b_M))^T \in \mathbb{R}^M \) the vector of unknowns. In matrix form, \( R \) is solution of an algebraic system with the structure

\[ \mathcal{A}(R) R = F, \text{ with } F = (f_1, \cdots, f_M)^T, \]

\[ f_i = \int_\Omega f \Pi_{\rho_h} \varphi_i \geq 0, \ i = 1, \cdots, M, \text{ for problem (9)} \]

\[ f_i = \int_\Omega f \varphi_i \geq 0, \ i = 1, \cdots, M, \text{ for problem (8)} \]
Once we know that this non-linear system has a solution, we deduce \( R = \mathcal{A}^{-1}(R) F \), and we reproduce the classical argument: As \( \mathcal{A}(R) \) is an M-matrix, then it is monotone so \( \mathcal{A}^{-1}(R) \) has non-negative entries and consequently \( R_i = \rho(b_i) \geq 0 \), \( i = 1, \ldots, M \). As \( \rho_h \) is piecewise linear, then \( \rho_h \geq 0 \) in \( \Omega \).

□

The obtention of \( L^r \) estimates, follow a duality argument developed in Brenner & Scott [7] that generalizes the classical one by Nitsche.

**Theorem 8.2** Assume that the family of triangulations \( \{T_h\}_{h>0} \) is regular. Assume also that \( f \in V' \) and \( u \in (L^q(\Omega))^d \) with \( q > 12 \). Assume finally that the advection-diffusion problem (1) is regular in the sense that its solution satisfies

\[
\|\rho\|_{2,+\infty} \leq C \|f\|_{V'}.
\]  

(41)

Then, the sequence of solutions of problem (8) \( \{\rho_h\} \) is bounded in \( L^r(\Omega) \), for all \( 1 \leq r < +\infty \). More specifically, there exists a constant \( C > 0 \) such that

\[
\|\rho_h\|_r \leq C \|f\|_{V'}.
\]

**Proof:**

The proof for \( 1 \leq r < 6 \) is a consequence of the theorem of Sobolev and the bound (26).

Consider the adjoint problem: For a given \( F \in V' \),

\[
\begin{aligned}
\text{Find } \sigma & \in V \text{ such that } \\
a(v, \sigma) = \langle F, v \rangle & \quad \forall v \in V,
\end{aligned}
\]

(42)

where \( a(\cdot, \cdot) \) is the bilinear form associated to the continuous problem (1), defined by (3).

Consider also the approximate dual problem on \( V_h \), by the standard Galerkin Finite Element method:

\[
\begin{aligned}
\text{Find } \sigma_h & \in V_h \text{ such that } \\
a(v_h, \sigma_h) = \langle F, v_h \rangle & \quad \forall v_h \in V_h.
\end{aligned}
\]

(43)

Under hypothesis (41), the following estimates hold for problems (1) (with \( g = 0 \)), (42) and (43) (Cf. [7]):

\[
\|\sigma\|_{1,q} \leq C_q \|F\|_q \quad \text{with } 1 < q \leq \infty,
\]

(44)

\[
\|\sigma_h\|_{1,r} \leq C_r \|\sigma\|_{W^{1,r}(\Omega)} \quad \text{with } 1 < r \leq \infty,
\]

(45)

for some positive constants \( C_q, C_r \).

We consider problem (43) with \( F = \text{sign}(\rho_h)|\rho_h|^{-1} \), that belongs to \( L^{r'} \) with \( \frac{1}{r} + \frac{1}{r'} = 1 \) and

\[
\|F\|_{r'} = \|\rho_h\|_{r}^{-1}.
\]

(46)
We set \( v_h = \rho_h \) in (43). Then we have
\[
\|\rho_h\|_r^r = a(\rho_h, \sigma_h).
\]
Also, as \( \rho \) is a solution of (1) and \( \rho_h \) is a solution of (8),
\[
a(\rho - \rho_h, \sigma_h) = a(\rho, \sigma_h) - a_h(\rho_h, \sigma_h) + a(\rho_h, \sigma_h) - a(\rho, \sigma_h) = \\
\left[ (u \cdot \nabla \rho_h, \Pi_{\rho h} \sigma_h) + \nu(\nabla \rho_h, \nabla \sigma_h) \right] \\
- \left[ (u \cdot \nabla \rho_h, \sigma_h) + \nu(\nabla \rho_h, \nabla \sigma_h) \right] = \delta_h,
\]
where \( a_h(\cdot, \cdot) \) is the bilinear form defined by (7) and
\[
\delta_h = (u \cdot \nabla \rho_h, \Pi_{\rho h} \sigma_h - \sigma_h) = (u \cdot \nabla (\rho_h - \rho), \Pi_{\rho h} \sigma_h - \sigma_h) + (u \cdot \nabla \rho, \Pi_{\rho h} \sigma_h - \sigma_h) = I + II \quad (47)
\]

**Estimate for I**

\[
|I| \leq \|u\|_q \|\nabla(\rho_h - \rho)\|_2 \|\Pi_{\rho h} \sigma_h - \sigma_h\|_{\tilde{q}} \leq \|u\|_q \|\nabla(\rho_h - \rho)\|_2 h \|\nabla \sigma_h\|_{\tilde{q}}, \quad (48)
\]
where \( \frac{1}{q} + \frac{1}{\tilde{q}} = 1 \), and we have used Lemma 5.2.
We can write the estimate (40) as
\[
\|\nabla(\rho_h - \rho)\|_2 \leq C_1 \|f\|_{V', h^{1 - \frac{3}{q}}} \]
As \( r \in [6, +\infty) \) and \( q > 12 \), we have \( r' < \tilde{q} \) and then an inverse inequality similar to (25) yields
\[
\|\nabla \sigma_h\|_{\tilde{q}} \leq C_2 h^{-3(\frac{1}{r'} - \frac{1}{q})} \|\nabla \sigma_h\|_{r'}
\]
Inserting this last estimate into (48) we obtain
\[
|I| \leq C_3 \|u\|_q \|f\|_{V', h^\gamma} \|\nabla \sigma_h\|_{r'}
\]
with \( \gamma = 2 - \frac{3}{q} - 3 \left( \frac{1}{r'} - \frac{1}{\tilde{q}} \right) = \frac{7}{2} - \frac{6}{q} - \frac{3}{r'} > \frac{1}{2} - \frac{6}{q} > 0 \), as \( q > 12 \) and \( r' > 1 \).

**Estimate for II**

Thanks to the regularity of the continuous solution, we have
\[
|II| \leq \|u\|_q \|\nabla \rho\|_m \|\Pi_{\rho h} \sigma_h - \sigma_h\|_{r'}
\]
with \( \frac{1}{m} = 1 - \frac{1}{q} - \frac{1}{r'} \).
Using (41) and Lemma 5.1, we deduce
\[
|II| \leq C_4 \|u\|_q \|f\|_{V'} \|\sigma_h\|_{r'}. \quad (49)
\]
Thus,

\[ |\delta_h| \leq C_5 \|u\|_q \|f\|_{V'}(1 + h^s) \|\nabla \sigma_h\|_{V'} \leq C_6 \|u\|_q \|f\|_{V'} \|F\|_{V'}, \]  

where we have used (44) and (45) in last estimate.

Going back to (47), applying (45) and (44) we obtain

\[ \|\rho_h\|_r = a(\rho_h, \sigma_h) = a(\rho, \sigma_h) - \delta_h \leq C_7 \|\rho\|_{1,r} \|\sigma_h\|_{1,r} - \delta_h \leq C_8 \|\rho\|_{1,r} \|F\|_{r'} + \delta_h. \]  

Then, using (46) and (50) we have

\[ \|\rho_h\|_r \leq C_9 \|f\|_{V'} \|F\|_{r'} \leq C_{10} \|f\|_{V'} \|\rho_h\|_{r^{-1}} \]  

So,

\[ \|\rho_h\|_r \leq C \|f\|_{V'}. \]

\[ \square \]

**Theorem 8.3** Assume that the family of triangulations \( \{T_h\}_{h>0} \) is regular. Assume also that \( f \in L^p(\Omega) \) for some \( p \geq 1 \), and \( u \in (L^q(\Omega))^d \) with \( q > 12 \). Assume finally that the advection-diffusion problem (1) is regular in the sense that its solution satisfies

\[ \|\rho\|_{2,\infty} \leq C \|f\|_p. \]  

Then, the sequence of solutions of problem (9) \( \{\rho_h\}_{h>0} \) is bounded in \( L^r(\Omega) \), for \( r \in [1, p] \). More specifically, there exists a constant \( C > 0 \) such that

\[ \|\rho_h\|_r \leq C \|f\|_p. \]

**Proof:** Proceeding as in Theorem 8.2 we obtain for \( \rho \) solution of (1) and \( \rho_h \) a solution of (9),

\[ a(\rho - \rho_h, \sigma_h) = a(\rho, \sigma_h) - a_h(\rho_h, \sigma_h) + a_h(\rho_h, \sigma_h) - a(\rho_h, \sigma_h) = (f, \sigma_h) - (f, \Pi_{\rho_h} \sigma_h) + [(u \cdot \nabla \rho_h, \Pi_{\rho_h} \sigma_h) + \nu(\nabla \rho_h, \nabla \sigma_h)] - [(u \cdot \nabla \rho_h, \sigma_h) + \nu(\nabla \rho_h, \nabla \sigma_h)] = \delta_h, \]

with

\[ \delta_h = (u \cdot \nabla \rho_h, \Pi_{\rho_h} \sigma_h - \sigma_h) + (f, \sigma_h - \Pi_{\rho_h} \sigma_h) = (u \cdot \nabla (\rho_h - \rho), \Pi_{\rho_h} \sigma_h - \sigma_h) + (u \cdot \nabla \rho, \Pi_{\rho_h} \sigma_h - \sigma_h) + (f, \sigma_h - \Pi_{\rho_h} \sigma_h) = I + II + III \]  

(53)
Estimate of I

This estimate is similar as that of I in Theorem 8.2 but we now use the error estimate (32) and then we have

\[ |I| \leq C_1 \|u\|_q \|f\|_p h^\gamma \|\nabla \sigma_h\|_{r'}, \]  

(54)

with \( \gamma = 2 - \frac{3}{q} - 3 \left( \frac{1}{r'} - \frac{1}{q} \right) > 0. \)

Estimate of II

Using (52) and Lemma 5.1, we deduce

\[ |II| \leq C_2 \|u\|_q \|f\|_p \|\sigma_h\|_{r'}. \]  

(55)

Estimate of III

\[ |III| \leq \|f\|_p \|\Pi_{\rho_h} \sigma_h - \sigma_h\|_{p'}. \]

As \( p \geq r \), then

\[ \|\Pi_{\rho_h} \sigma_h - \sigma_h\|_{p'} \leq \|\Pi_{\rho_h} \sigma_h - \sigma_h\|_{r'} \]

and using Lemma 5.1, we deduce

\[ |III| \leq C_3 \|f\|_p \|\sigma_h\|_{r'}. \]  

(56)

Going back to (53) and using (54), (55) and (56) we obtain

\[ |\delta_h| \leq C_1 \|u\|_q \|f\|_p h^\gamma \|\nabla \sigma_h\|_{r'} + C_2 \|u\|_q \|f\|_p \|\sigma_h\|_{r'} + C_3 \|f\|_p \|\sigma_h\|_{r'}. \]

From this estimate for \( \delta_h \) we proceed as in Theorem 8.2 and conclude the proof.

\[ \square \]

Remark 8.1 The hypotheses (41) on the regularity of the advection-diffusion problem (1) is obtained for instance if \( u \in L^\infty(\Omega) \) and \( \Omega \) is convex. This hypothesis is needed to deduce estimate (44) (Cf. [4], [7]).

9 Order of accuracy and well-balanced property

A question that naturally arises after the preceding analysis is to determine the order of accuracy of the PSI method in low-order norms, in particular in \( L^2(\Omega) \) norm.

We may use the standard Nitsche duality argument to estimate this error, using the re-formulations (8) or (9) of the PSI method as a variational method, as we have done in
the proof of Theorem 8.2. However, this procedure only yields first-order accuracy, due to the first-order error stemming from the Distribution Interpolation of the test functions. This does not necessarily indicates that the convergence order in $L^2(\Omega)$ norm can not be better than the first order obtained for the $H^1(\Omega)$ norm. To test this question we have approximated the advection-diffusion problem (1) in a simple but meaningful $\mathbb{R}^2$ test, when this has a $C^\infty(\Omega)$ solution, and $\Omega$ is the unit square. Specifically, we have considered:

**Test 1**

$$u = (1, 0), \quad f = ye^{x+y}[(y-1)(x^2 + x - 1) - 2x \nu(xy + x + y - 3)], \quad g = 0.$$  

The exact solution is

$$\rho(x, y) = xy(x-1)(y-1)e^{x+y}.$$  

We have solved this problem with the PSI method (9) on non-structured grids. This ensures the distribution of the flux and the genuine non-linear nature of the PSI method for this test. This would not had been the case if we had used structured grids for this particular velocity $u = (1, 0)$.

We have estimated the order of convergence in $L^q(\Omega)$ norm by means of the numerical solutions $\rho_h$ and $\rho_{2h}$ computed on two meshes of sizes $h$ and $2h$, respectively, as

$$p^h_{L^q} \simeq \log_2 \left( \frac{\|\rho - \rho_{2h}\|_{L^2(\Omega)}}{\|\rho - \rho_h\|_{L^2(\Omega)}} \right).$$  

Similarly, the convergence order in $H^1(\Omega)$ norm has been estimated by

$$p^h_{H^1} \simeq \log_2 \left( \frac{\|\nabla(\rho - \rho_{2h})\|_{L^2(\Omega)}}{\|\nabla(\rho - \rho_h)\|_{L^2(\Omega)}} \right).$$

Table 1 shows the estimated convergence orders in $L^2(\Omega)$, $L^\infty(\Omega)$ and $H^1(\Omega)$ norms, for $h = 1/N$ with $N = 40, 80$ and $160$, where $N$ denotes the number of subdivisions on each side of $\Omega$. We observe that all orders of convergence are close to 1. Although our grids are non-structured, and then we cannot expect a very smooth behaviour of the estimated convergence order, this value roughly approaches the value 1 as $h$ decreases.

As the solution is very smooth and the domain is convex, then the standard Galerkin Finite Element approximation of problem (1) yields a second order accuracy in $L^2(\Omega)$ norm. However, this does not seem the case for the PSI method in view of our results.

Table 1: Convergence orders for PSI method, Test 1.
Nevertheless, our Petrov-Galerkin formulation allows to prove another remarkable property of the upwindered formulation (9): Its well-balanced character for advection-dominated regimes. To give a rigorous definition of this property, let us consider a solution of problem (1), and define the consistency error $\epsilon(\rho) \in V'_h$

$$
\langle \epsilon(\rho), v_h \rangle = \int_{\Omega} (u \cdot \nabla \rho) \Pi_{r_h} v_h + \nu \int_{\Omega} \nabla \rho \cdot \nabla v_h - \int_{\Omega} f \Pi_{r_h} v_h,
$$

where $r_h \in V_h$ is some interpolant of $\rho$.

**Definition 9.1 (Well-balanced scheme)**

Consider a smooth solution $\rho$ of the advection-diffusion problem (1).

- We say that the numerical scheme (9) is well-balanced for the solution $\rho$ if $\epsilon(\rho) = 0$.
- We say that the numerical scheme (9) is well-balanced for the solution $\rho$ up to order $p > 0$ if $\|\epsilon(\rho)\|_{V'_h} = O(h^p)$.

For $p = 2$, this property is the adaptation to our context of the “Second-order accuracy at steady state” property stated in [3]. This property is cited as a basic design principle for conservative schemes to solve hyperbolic systems of conservation laws.

In the context of numerical solution of Shallow Water equations, for instance, this property helps to design accurate schemes. It ensures, in particular, that water at rest is solved with high accuracy if $p \geq 2$ (See Bermúdez & Vázquez-Cendón [5], Chacón et al. [10]).

Let us remember the definition of the Péclet and grid Péclet numbers,

$$
Pe = \frac{U}{\nu}, \quad Pe_h = \frac{U}{\nu},
$$

where $U$ and $L$ respectively are a characteristic speed and length of the flow. The Péclet number measures the relative balance between the convective and the diffusive terms in equation (1). The advection-diffusion process is said to occur in *advection dominated* regime—withe respect to the current grid—if $Pe_h \geq 1$.

**Lemma 9.1** The upwinded PSI scheme (9) is

- Exactly well-balanced for the advection equation

$$
\begin{align*}
\left\{ 
\begin{array}{ll}
u \cdot \nabla \rho = f & \text{in } \Omega, \\
\rho = g & \text{on } \Gamma^-,
\end{array}
\right.
\end{align*}
$$

and

- Well-balanced up to second order for the advection-diffusion equation (1) when the flow takes place in advection-dominated regime.
Proof:

- **Transport equation.** This is a direct consequence of the upwinded structure of scheme (9). Indeed, the consistency error acts as

\[ \langle \epsilon(\rho), v_h \rangle = \int_{\Omega} (v \cdot \nabla \rho - f) \Pi_{r_h} v_h = 0, \forall v_h \in V_h. \]

- **Advection-diffusion equation.** Let us assume for simplicity that equation (1) is written in adimensional quantities. In this case, \( Pe = 1/\nu \) and \( Pe_h = h/\nu \).

Assume \( \rho \in H^2(\Omega) \). Using integration by parts, \( \forall v_h \in V_h \),

\[ \langle \epsilon(\rho), v_h \rangle = \int_{\Omega} (u \cdot \nabla \rho - \nu \Delta \rho - f) \Pi_{r_h} v_h + \nu \int_{\Omega} \Delta \rho (\Pi_{r_h} v_h - v_h). \]

Then, by Lemma 5.2

\[ |\langle \epsilon(\rho), v_h \rangle| \leq \nu \|\Delta \rho\|_2 \|\Pi_{r_h} v_h - v_h\|_2 \leq \nu h \|\Delta \rho\|_2 \|\nabla v_h\|_2. \]

So \( \|\epsilon(\rho)\|_{V_h} \leq \nu h \|\Delta \rho\|_2 \). Using that \( Pe_h \geq 1 \),

\[ \|\epsilon(\rho)\|_{V_h} \leq \nu h Pe_h \|\Delta \rho\|_2 \leq \|\Delta \rho\|_2 h^2. \]

□

Similarly, it may be proved that the scheme (8) is well-balanced up to second order for flows in diffusion-dominated regime, when \( \nu \geq C U h^{-1} \).
