EMOTIONAL AUTONOMY, PARENT INVOLVEMENT AND FLOURISHING DURING EMERGING ADULTHOOD IN SPAIN

Parra, A., García, M. C., Sánchez-Queija, I. & Díez, M.
Department of Developmental and Educational Psychology, University of Seville, Spain

In recent years, emotional autonomy from parents has been largely studied, with inconclusive results, to determine whether it is truly part of a developmental stage during adolescence and emerging adulthood, or if it is an indicator of difficult family relationships. There are also non-conclusive results regarding the relationship between emotional autonomy from parents and personal well-being. The situation in Spain about young people would be represented by the Mediterranean model. Spanish young people remain in the parental home for extended periods and tend to make direct transitions from living at home to marriage and parenthood. So we consider especially interesting studying emotional autonomy from parents in a Mediterranean country such as Spain.

AIMS

1st To know if emotional autonomy from parents is related to positive family relationships during emerging adulthood or it is an indicator of negative family relationships.
2nd To know if emotional autonomy from parents is related to emerging adults wellbeing.

We believe relevant to divide the sample into two groups.
- Emerging adults between 18 and 22 years old. In Spain most young people at that ages continue with their education.
- Emerging adults between 23 and 29 years old. Young people of that age are usually closer to the work setting.

RESULTS

Figure 1. Emotional Autonomy by sex

DISCUSSION

- Boys showed higher levels of Emotional Autonomy than girls. Probably, girls feel more pressure from the family than boys in Spain.

- A higher level of Emotional Autonomy seems to be the result of difficult family relationships. In fact, the most autonomous emerging adults were those that presented lower levels of parental involvement throughout emerging adulthood.

- Emotional Autonomy is negatively correlated with flourishing and positively correlated with tobacco and hashish/marijuana consumption specially at the beginning of emerging adulthood. Emotional Autonomy from parents could be a risk factor for emerging adults’ well-being especially at the beginning of the stage. The negative influence of this emotional distance seems to decline with age.
