   - Maximum Principle
   - Strong solution?
   - Local weak regularity for \((\partial_t u, \partial_t Q)\) and uniqueness
Complex Fluids

It is not possible to decouple microscopic and macroscopic effects.

- **Fluids with elastic properties.** They possess intermediate properties between solids and liquids. Examples: liquid crystals, polymers (macromolecules), ...

- **Phase-field models.**
  Examples: multi-fluids (mixture of fluids), multi-phases (solidification), ...

These complex materials have practical utilities because its microstructure can be handled in order to produce good mechanical, optical or thermic properties.
Liquid Crystals

Liquid crystals (LC) are intermediate phases between solid and liquid; at the macroscopic level, they are (viscous) liquids but their molecules have a anisotropic order due to their elastic properties.

- **Nematic Liquid Crystals** have an orientation order.
- **Smectic Liquid Crystals** have also a positional order (arranged by layers).

The derivation and the analysis falls into a general energetic variational framework for complex fluids with elastic effects due to the presence of nontrivial microstructures, coupling

- Navier-Stokes equations for the velocity and pressure.
- Partial Differential Equations for the microscopic variable (called order parameter).

Director field $\mathbf{d}(t, x)$, representing the average orientation of the liquid crystal molecules.

The shear stress tensor depends on elastic and viscous effects (Ericksen-Leslie theory, 1980s):

$$
\sigma = \sigma^d(D, \mathbf{d}) + \lambda \sigma^e(\mathbf{d}),
$$

where $\sigma^d$ is the dissipative tensor, $\sigma^e$ the elastic tensor and $\lambda > 0$ a “balance” coefficient.

Then, equations for equilibrium of forces remains as:

$$
D_t \mathbf{u} + \nabla p - \nabla \cdot \sigma^d - \lambda \nabla \cdot \sigma^e = 0 \quad \text{in } Q = (0, T) \times \Omega.
$$
Nematic Liquid Crystals: Microscopic Model (of Allen-Canh’s type)

Starting from the Ericksen-Leslie’s formulation, a penalized model is presented by [F.H. Lin]:

\[ \mathcal{D}_t \mathbf{d} + \gamma \frac{\delta E_e}{\delta \mathbf{d}} = 0, \text{ in } Q, \]

where

\[ \frac{\delta E_e}{\delta \mathbf{d}} = -\Delta \mathbf{d} + \nabla \mathbf{d} F_\epsilon (\mathbf{d}) \]

is the Euler-Lagrange equation associated to the elastic energy functional:

\[ E_e (\mathbf{d}) = \left( \frac{1}{2} \int_\Omega |\nabla \mathbf{d}|^2 + \int_\Omega F_\epsilon (\mathbf{d}) \right) \]
Ginzburg-Landau’s functional:

\[ F_\epsilon (d) = \frac{1}{4 \epsilon^2} \left( |d|^2 - 1 \right)^2 \]

such that \( f_\epsilon (d) = \nabla_d (F_\epsilon (d)) \) for every \( d \in \mathbb{R}^3 \), hence

\[ f_\epsilon (d) = \frac{1}{\epsilon^2} \left( |d|^2 - 1 \right) d, \]

where \( |d| \) denotes the euclidean norm in \( \mathbb{R}^3 \) and \( \epsilon > 0 \) is a penalization parameter.
A simplified model [F. H. Lin]

Taking

\[ \sigma^d = \nu (\nabla u + \nabla u^t) \quad \text{(Stokes' law)} \]

\[ \sigma^e = - (\nabla d)^t \nabla d \quad \Rightarrow \quad \nabla \cdot \sigma^e = (\nabla d)^t (-\Delta d + f_\epsilon (d)) + \nabla (\cdots) \]

\[
\begin{align*}
\partial_t u + u \cdot \nabla u - \nu \Delta u + \nabla \tilde{\rho} &= -\lambda (\nabla d)^t \Delta d \\
\nabla \cdot u &= 0 \\
\nabla d + u \cdot \nabla d + \gamma (-\Delta d + f_\epsilon (d)) &= 0 \\
\left. u \right|_{\partial \Omega} &= 0, \quad \left. d \right|_{\partial \Omega} = d_{\partial \Omega} \\
\left. u \right|_{t=0} &= u_0, \quad \left. d \right|_{t=0} = d_0
\end{align*}
\]

F. Guillén-Gonzalez, EDAN and IMUS, Univ. Sevilla
DIMO2013
Free energy

Free energy operator:

\[ \mathcal{E}(Q) = \int_\Omega \frac{\varepsilon}{2} |\nabla Q|^2 + F(Q) \]

where

\[ F(Q) = \frac{a}{2} |Q|^2 - \frac{b}{3} (Q^2 : Q) + \frac{c}{4} |Q|^4 \quad \text{(non-convex)} \quad (1) \]

Let \( H(Q) = \frac{\delta \mathcal{E}(Q)}{\delta Q} \) be the variational derivative in \( L^2(\Omega) \).
Velocity system

The variables describing the (QT)-model are 
\((u, Q, p) : (0, T) \times \Omega \rightarrow \mathbb{R}^3 \times \mathbb{R}^{3 \times 3} \times \mathbb{R}\):

\[
\begin{aligned}
D_t u - \nu \Delta u + \nabla p &= \nabla \cdot \tau(Q) + \nabla \cdot \sigma(H, Q) \quad \text{in } \Omega \times (0, T) \\
\nabla \cdot u &= 0 \quad \text{in } \Omega \times (0, T)
\end{aligned}
\]

where \(D_t u = \partial_t u + (u \cdot \nabla) u\) is the material derivative,

\[
\begin{aligned}
\tau_{ij}(Q) &= -\varepsilon \left( \partial_j Q : \partial_i Q \right) = -\varepsilon \partial_j Q_{kl} \partial_i Q_{kl}, \quad \varepsilon > 0 \\
\sigma(H, Q) &= H Q - Q H
\end{aligned}
\]

(symmetric part)

(antisymmetric part when \(Q\) and \(H\) are symmetric)
Q-tensor system

\[ \partial_t Q + (u \cdot \nabla) Q - S(\nabla u, Q) = -\gamma H(Q) \quad \text{in } \Omega \times (0, T) \]

where

\[
\begin{aligned}
S(\nabla u, Q) &= \nabla u \, Q^t - Q^t \, \nabla u, \quad \text{(stretching term)} \\
H(Q) &= -\varepsilon \Delta Q + f(Q) \quad \text{where} \\
f(Q) &= a Q - \frac{b}{3} \left( Q^2 + QQ^t + Q^t Q \right) + c |Q|^2 Q \\
\text{with } c > 0, \ a, \ b \in \mathbb{R} \\
(H \text{ is a symmetric tensor if } Q \text{ is symmetric,} \ \text{in fact } f(Q)^t = f(Q^t))
\end{aligned}
\]
Previous results for an initial-value problem (in the whole $\mathbb{R}^3$) [Paicu-Zarnescu’12]

- Existence of weak solution in $(0, T)$, for each $T > 0$.
- Global strong solution in 2D.
- Weak-Strong uniqueness
Initial and boundary conditions

Initial conditions:

\[ u|_{t=0} = u_0, \quad Q|_{t=0} = Q_0 \quad \text{in } \Omega, \]

Boundary conditions (\( \Gamma = \partial \Omega \)): 

- For the velocity: \( u|_{\Gamma} = 0 \) in \((0, T)\).
- For the \( Q \)-tensor:
  \[ \partial_n Q|_{\Gamma} = 0 \quad \text{or} \quad Q|_{\Gamma} = Q_{\Gamma} \quad \text{in } (0, T). \]
Main results for the initial-boundary QT-model

- existence of global in time weak solution (without using maximum principle).
- Modification of the model to enforce traceless and symmetry constraints for $Q$.
- maximum principle
- uniqueness criteria for weak solutions
- local existence (and uniqueness) of a “intermediate” regular solution
1. Nematic Liquid Crystals
   - A simplified model by F. H. Lin
   - Some known results

2. Models with Stretching Terms
   - Nematic Liquid Crystals with Stretching Terms
   - A generic Q-tensor model

3. Some analytical results for Q-tensor models
   - Weak existence
   - Weak/strong uniqueness
   - Maximum Principle
   - Strong solution?
   - Local weak regularity for \((\partial_t u, \partial_t Q)\) and uniqueness

F. Guillén-Gonzalez, EDAN and IMUS, Univ. Sevilla
DIMO2013
Step 1. Energy equality (Lyapunov functional)

\[
\frac{d}{dt} \left( \frac{1}{2} \|u\|^2_{L^2(\Omega)} + \mathcal{E}(Q) \right) + \nu \|\nabla u\|^2_{L^2(\Omega)} + \gamma \|H(Q)\|^2_{L^2(\Omega)} = 0,
\]

with \( \mathcal{E}(Q) = \int_\Omega \frac{\varepsilon}{2} |\nabla Q|^2 + F(Q) \, dx \geq 0 \)

Using that:

\[
(S(\nabla u, Q), H(Q))_{L^2} = (\sigma(H, Q), \nabla u)_{L^2} \\
(u \cdot \nabla Q, H(Q))_{L^2} = (\nabla \cdot \tau(Q), u)_{L^2}
\]

\( Q \)-system \hspace{1cm} \( u \)-system
Step 2. Lower bound of the potential

But the term $F(Q)$ could be negative. Observe that:

$$F(Q) \geq \begin{cases} \frac{a}{2} |Q|^2 + \frac{c}{8} |Q|^4 - \alpha_1, & \text{for } \alpha_1 = \alpha_1(b, c) > 0 \text{ if } a > 0, \\ \frac{c}{8} |Q|^4 - \alpha_2 - \beta, & \text{for } \alpha_2 = \alpha_2(b, c), \beta = \beta(a, c) > 0 \text{ if } a < 0, \end{cases}$$

Defining $\tilde{F}(Q) = F(Q) + \mu$ with $\mu = \alpha_1$ if $a \geq 0$ and $\mu = \alpha_2 + \beta$ if $a < 0$, then:

$$\tilde{F}(Q) \geq \begin{cases} \frac{a}{2} |Q|^2 + \frac{c}{8} |Q|^4 \geq 0 & \text{if } a > 0, \\ \frac{c}{8} |Q|^4 \geq 0 & \text{if } a < 0, \end{cases}$$
Step 3. Weak regularity

\[
\frac{1}{2} \| \mathbf{u}(t) \|^2_{L^2(\Omega)} + \frac{\varepsilon}{2} \| \nabla Q(t) \|^2_{L^2(\Omega)} + \int_{\Omega} \tilde{F}(Q(t)) < +\infty,
\]
(here, \(|\Omega| < +\infty \) is essential).

Therefore:

\[
\begin{aligned}
\mathbf{u} &\in L^\infty(0, +\infty; L^2(\Omega)) \cap L^2(0, +\infty; H^1(\Omega)), \\
\nabla Q &\in L^\infty(0, +\infty; L^2(\Omega)) \\
\tilde{F}(Q) &\in L^\infty(0, +\infty; L^1(\Omega)) \\
-\varepsilon \Delta Q + f(Q) &\in L^2(0, +\infty; L^2(\Omega))
\end{aligned}
\]

Finally

\[
Q \in L^\infty(0, +\infty; H^1(\Omega)), \quad Q \in L^2(0, T; H^2(\Omega)), \quad \forall T > 0.
\]
Replace

\[ H \text{ by } \tilde{H} = H + \alpha(Q)Id \]

with \( \alpha(Q) = \frac{1}{3} \left( -a \text{ tr}(Q) + \frac{b}{3} (\text{tr}(Q^2) + 2|Q|^2) \right) \) or \( \alpha(Q) = -\frac{1}{3} \text{tr}(f(Q)) \)

Idea: To eliminate the non-convex part (at least) of the trace of \( Q \)-system
Modifications of the model to enforce symmetry

Replace

\[ S(\nabla u, Q) \text{ by } S(W(u), Q), \]

with \( W(u) = (\nabla u + \nabla u^t)/2 \)

Idea: To eliminate the symmetric part of the stretching term of \( Q \)-system

F. Guillén-Gonzalez, EDAN and IMUS, Univ. Sevilla
DIMO2013
Uniqueness criteria

Let \((u_1, q_1, Q_1, H^1_c), (u_2, q_2, Q_2, H^2_c)\) be two solutions,
\((H^i_c)^i = -\varepsilon \Delta Q_i + F'_c(Q_i))\), for \(F = F_c + F_e\)
\(u = u_1 - u_2, q = q_1 - q_2, Q = Q_1 - Q_2, H_c = H^1_c - H^2_c\).

\[
\frac{1}{2} \frac{d}{dt} \left( \|u\|^2_{L^2(\Omega)} + \varepsilon \|Q\|^2_{H^1(\Omega)} + \int_\Omega Q_{mn} \frac{\partial^2 F_c(R)}{\partial Q_{mn} \partial Q_{pq}} Q_{pq} \, dx \right) \\
+ \nu \|\nabla u\|^2_{L^2(\Omega)} + \gamma \|H_c\|^2_{L^2(\Omega)} \\
\leq C(t) \left( \|u\|^2_{L^2(\Omega)} + \varepsilon \|Q\|^2_{H^1(\Omega)} \right)
\]

where \(C(t) \in L^1(0, T)\) under the regularity hypothesis:

\[
(RH) \begin{cases} \nabla u_2 \in L^{\frac{2q}{2q-3}}(0, T; L^q(\Omega)), & \text{for } 2 \leq q \leq 3 \\ \Delta Q_2 \in L^{\frac{2r}{2r-3}}(0, T; L^r(\Omega)), & \text{for } 2 \leq r \leq 3 \end{cases}
\]

   - Strong solution?
   - Local weak regularity for $(\partial_t u, \partial_t Q)$ and uniqueness

F. Guillén-Gonzalez, EDAN and IMUS, Univ. Sevilla
DIMO2013
Maximum Principle

Based on:

1. \( S(\nabla u, Q) : Q = 0 \)

2. \( f(Q) : Q \geq \frac{c}{2} |Q|^2 \left( |Q|^2 - \beta \right) \text{ for } \beta = \frac{b^2}{c^2} - \frac{2a}{c} \).

Then,

\[
\partial_t \left( |Q|^2 \right) + u \cdot \nabla \left( |Q|^2 \right) - \gamma \varepsilon \Delta \left( |Q|^2 \right) + \gamma \frac{c}{2} |Q|^2 \left( |Q|^2 - \beta \right) \leq 0
\]

If \( \|Q_0\|_{L^\infty(\Omega)} \leq \alpha \) (and \( \|Q_\Gamma\|_{L^\infty(\Gamma)} \leq \alpha \)) with \( \alpha \geq \beta \), then:

\[
\|Q(t)\|_{L^\infty(\Omega)} \leq \alpha \quad \forall t \geq 0.
\]

   - Weak existence
   - Weak/strong uniqueness
   - Maximum Principle
   - Strong solution?
   - Local weak regularity for \((\partial_t u, \partial_t Q)\) and uniqueness
Problems with the strong regularity

- **Prodi’s (space) estimates** (taking $-\Delta u$ for $u$-system and $-\Delta (-\varepsilon \Delta Q + f(Q))$ for $Q$-system) **only works for**
  1. periodic-space boundary conditions for $Q$,
  2. large enough viscosity.

- **Modified Ladyzhenskaya’s (time) estimates** works for Neumann and Dirichlet boundary conditions for $Q$. 
The key point for Prodi’s estimates

Due to the boundary condition for $Q$ (non space-periodic):

$$(S(\nabla u, Q), -\Delta H(Q))_{L^2} \neq (\sigma(H, Q), \nabla(-\Delta u))_{L^2}$$

and

$$(\nabla \cdot \tau(Q), -\Delta u)_{L^2} \neq (u \cdot \nabla Q, -\Delta H(Q))_{L^2}$$

because some (high nonlinear) boundary terms don’t vanish.
The bad terms (only bounded for large viscosity)

\[
\frac{1}{2} \frac{d}{dt} \left( \| \nabla u \|_{L^2(\Omega)}^2 + \| \Delta Q \|_{L^2(\Omega)}^2 \right) + \nu \| Au \|_{L^2(\Omega)}^2 + \gamma \| \nabla (\Delta Q) \|_{L^2(\Omega)}^2 \\
= - (u \cdot \nabla u, Au) + (Au \cdot \nabla Q, \Delta Q) + (\nabla \cdot \sigma, Au) + \ldots \\
-(\nabla (u \cdot \nabla Q), \nabla (\Delta Q)) + (\nabla S(\nabla u, Q), \nabla (\Delta Q)) \\
\leq \ldots + \int_{\Omega} |Q| |\nabla (\Delta Q)| |Au| \ dx \leq \ldots 
\]
Nematic Liquid Crystals
Models with Stretching Terms
Some analytical results for $Q$-tensor models

1. Nematic Liquid Crystals
   - A simplified model by F. H. Lin
   - Some known results

2. Models with Stretching Terms
   - Nematic Liquid Crystals with Stretching Terms
   - A generic $Q$-tensor model

3. Some analytical results for $Q$-tensor models
   - Weak existence
   - Weak/strong uniqueness
   - Maximum Principle
   - Strong solution?
   - Local weak regularity for $(\partial_t u, \partial_t Q)$ and uniqueness
Modified Ladyzhenskaya’s estimates

**Weak estimates for \((\partial_t u, \partial_t Q)\)**

Deriving in time \(u\)-system and \(Q\)-system, and taking \(\partial_t u\) and 
\(-\Delta (\partial_t Q)\) as test functions:

\[
\frac{d}{dt} \left( \|\partial_t u\|_{L^2(\Omega)}^2 + \varepsilon \|\partial_t Q\|_{H^1(\Omega)}^2 \right) \\
+ \nu \|\partial_t u\|_{H^1(\Omega)}^2 + \gamma \varepsilon^2 \|\partial_t Q\|_{H^2(\Omega)}^2 \\
\leq a(t) \left( \|\partial_t u\|_{L^2(\Omega)}^2 + \|\partial_t Q\|_{H^1(\Omega)}^2 \right) \\
+ C_{\nu, \gamma, \varepsilon} \left( \|\nabla u\|_{L^2(\Omega)}^4 + \|H\|_{L^2(\Omega)}^4 \right) \left( \|\partial_t u\|_{L^2(\Omega)}^2 + \|\partial_t Q\|_{H^1(\Omega)}^2 \right)
\]

where \(a \in L^1(0, T)\) (due to weak estimates).
Intermediate strong estimates for $Q$

Taking $\partial_t H = \partial_t (-\varepsilon \Delta Q + f(Q))$ as test function in the $Q$-system:

$$\gamma \frac{d}{dt} \|H\|_{L^2(\Omega)}^2 + \varepsilon \|\partial_t (\nabla Q)\|_{L^2(\Omega)}^2 \leq C_\delta \left(1 + \|Q\|_{H^2(\Omega)}\right) \|\partial_t Q\|_{L^2(\Omega)}^2$$

$$+ \delta \|\partial_t H\|_{L^2(\Omega)}^2 + C_\delta \|Q\|_{H^2(\Omega)} \|\nabla u\|_{L^2(\Omega)}^2$$

(3)
Intermediate strong estimates for $u$

Taking $\partial_t u$ as test function in the equation for $u$:

$$
\nu \frac{d}{dt} \| \nabla u \|_{L^2(\Omega)}^2 + \| \partial_t u \|_{L^2(\Omega)}^2 \\
\leq C \left( \| \nabla u \|_{L^2(\Omega)}^3 + \| Q \|_{H^2(\Omega)} \| H \|_{L^2(\Omega)}^2 \right)
$$

(4)
Weak-t estimates

Putting together (2)-(3)-(4), we get:

\[ y'(t) + z(t) \leq \tilde{a}(t) y(t) + C y(t)^3 \]

where

\[
\begin{align*}
  y(t) & = \| \partial_t u \|_{L^2(\Omega)}^2 + \| \partial_t Q \|_{H^1(\Omega)}^2 + \| \nabla u \|_{L^2(\Omega)}^2 + \| H \|_{L^2(\Omega)}^2 \\
  z(t) & = \| \partial_t u \|_{H^1(\Omega)}^2 + \| \partial_t Q \|_{H^2(\Omega)}^2
\end{align*}
\]
Intermediate regularity results

Thus, we obtain:

- Local in time weak solution for \((\partial_t u, \partial_t Q)\):

\[
\begin{cases}
\partial_t u \in L^\infty(0, T^*; L^2(\Omega)) \cap L^2(0, T^*; H^1(\Omega)) \\
\partial_t Q \in L^\infty(0, T^*; H^1(\Omega)) \cap L^2(0, T^*; H^2(\Omega)) \\
u \in L^\infty(0, T^*; H^1(\Omega)) \\
Q \in L^\infty(0, T^*; H^2(\Omega))
\end{cases}
\]

and uniqueness !! (because uniqueness criteria \((RH)\) is satisfied for \(q = 2\) and \(r = 2\).)

- Under regularity hypothesis \((RH)\), global in time weak solution for \((\partial_t u, \partial_t Q)\).
Intermediate regularity results

Thus, we obtain:

- Local in time weak solution for \((\partial_t u, \partial_t Q)\):

\[
\begin{align*}
\partial_t u &\in L^\infty(0, T^*; L^2(\Omega)) \cap L^2(0, T^*; H^1(\Omega)) \\
\partial_t Q &\in L^\infty(0, T^*; H^1(\Omega)) \cap L^2(0, T^*; H^2(\Omega)) \\
u &\in L^\infty(0, T^*; H^1(\Omega)) \cap L^2(0, T^*; H^2(\Omega)) \ ? \\
Q &\in L^\infty(0, T^*; H^2(\Omega)) \cap L^2(0, T^*; H^3(\Omega)) \ ?
\end{align*}
\]

and uniqueness !! (because uniqueness criteria \((RH)\) is satisfied for \(q = 2\) and \(r = 2\).)

- Under regularity hypothesis \((RH)\), global in time weak solution for \((\partial_t u, \partial_t Q)\).

Local weak regularity for $(\partial_t u, \partial_t Q)$ and uniqueness

Why long-time behavior for intermediate regularity is not clear

Using Prodi’s estimates, we would have the following generic situation (without stretching):

(weak)  $E'(t) + F(t) \leq 0$

(strong) $F'(t) + G(t) \leq C_2(F(t)^3 + 1)$

$\left\{ \begin{array}{l}
E(t) = \|u\|_{L^2(\Omega)}^2 + \|\nabla Q\|_{L^2(\Omega)}^2, \\
F(t) = \|\nabla u\|_{L^2(\Omega)}^2 + \|H\|_{L^2(\Omega)}^2, \\
G(t) = \|Au\|_{L^2(\Omega)}^2 + \|\nabla H\|_{L^2(\Omega)}^2.
\end{array} \right.$

$\Rightarrow \exists \lim_{t \to +\infty} F(t) = 0.$

[B. Climent-Ezquerra, F.G-G, M.A.Rodriguez-Bellido’10]
Why long-time behavior for intermediate regularity is not clear

We have the following generic situation for $t \in (0, +\infty)$:

(weak) $E'(t) + F(t) \leq 0$

(strong) $\tilde{F}'(t) + \tilde{G}(t) \leq C_2(\tilde{F}(t)^3 + 1)$

\[
\begin{align*}
E(t) &= \|u\|_{L^2(\Omega)}^2 + \|\nabla Q\|_{L^2(\Omega)}^2, \\
F(t) &= \|\nabla u\|_{L^2(\Omega)}^2 + \|H\|_{L^2(\Omega)}^2,
\end{align*}
\]

\[
\begin{align*}
\tilde{F}(t) &= \|\nabla u\|_{L^2(\Omega)}^2 + \|H\|_{L^2(\Omega)}^2 + \|\partial_t u\|_{L^2(\Omega)}^2 + \|\partial_t Q\|_{H^1(\Omega)}^2, \\
\tilde{G}(t) &= \|\partial_t u\|_{H^1(\Omega)}^2 + \|\partial_t Q\|_{H^2(\Omega)}^2.
\end{align*}
\]
Final comment

This methodology can be extended to a more general $Q$-tensor model and Erickseen-Leslie nematic models, and could be applicable to other Diffuse-Interface models.

Some open problems

1. To design “energy-stable” numerical schemes, by using traceless and symmetry.
2. Global in time intermediate regular solutions with “explicit” conditions for initial data.
3. Local in time strong regularity.

Nematic Liquid Crystals
Models with Stretching Terms
Some analytical results for $Q$-tensor models

- Weak existence
- Weak/strong uniqueness
- Maximum Principle
- Strong solution?
- Local weak regularity for $(\partial_t u, \partial_t Q)$ and uniqueness
