Abstract. Latin squares of order $n$ are equivalent to 1-factorizations of $K_{n,n}$. In this way, fixed a principal isotopism $\Theta = (\alpha, \beta, \varepsilon) \in S_n^3$, where $S_n$ is the symmetric group of the set $N = \{0, 1, \ldots, n-1\}$, we are going to study in this paper the set of graphs related to $\Theta$ when this last one is a principal autotopism of a Latin square. To do it, the number $\Delta_K(\Theta)$ of reduced Latin squares having $\Theta$ as a principal autotopism is studied.

Keywords. Latin square, Autotopism group, 1-factorization.

1. Introduction

Fixed a graph $G = (V, E)$, a 1-factor $f$ of $G$ is a subgraph of $G$ with the same set $V$ of vertices that $G$ and whose edges are a subset $E_f$ of $E$ such that every vertex has exactly one edge incident on it. If $E$ can be partitioned into disjoint subsets decomposing $G$ into 1-factors, then $G$ is said to be 1-factorizable and this partition $F$ is said to be a 1-factorization of $G$. An isomorphism from a 1-factorization $F = [f_0, f_1, \ldots, f_{n-1}]$ of a graph $G$ to a 1-factorization $F' = [f'_0, f'_1, \ldots, f'_{n-1}]$ of a graph $G'$ is a pair $(\Phi, \pi)$, where $\Phi$ is a bijection between the vertices of $G$ and $G'$ and $\pi : S \to S$ is a permutation of the elements of the set $S = \{0, 1, \ldots, n-1\}$, such that $\Phi(E_{f_i}) = E'_{f'_{\pi(i)}}$ for all $i \in N$.

A Latin square $L$ of order $n$ is an $n \times n$ array with elements chosen from a set $N = \{x_1, \ldots, x_n\}$, such that each symbol occurs precisely once in each row and each column. The set of Latin squares of order $n$ is denoted by $LS(n)$. In this paper we will consider $N = \{0, 1, \ldots, n-1\}$. So, if $L = (l_{ij})$, the orthogonal array representation of $L$ is the set of $n^2$ triples $\{(i, j, l_{ij}) : i, j \in N\}$. By permuting in the same way the coordinates in each one of these triples, it is obtained one of the six conjugate Latin squares associated to $L$. $L = (l_{ij})$ is a reduced Latin square if $l_{ik} = k = l_{ki}$ for all $k \in N$. The set of reduced Latin squares of order $n$ is denoted by $RLS(n)$. A partial Latin square $P$ of order $n$ is a $n \times n$ array with elements chosen from a set of $n$ symbols, such that each symbol occurs at most
once in each row and in each column. The set of partial Latin squares of order \( n \) is denoted by \( PLS(n) \). An isomorphism of a Latin square \( L \) is a triple \( \Theta = (\alpha, \beta, \gamma) \in J_n = S_n \times S_n \times S_n \), where \( S_n \) is the symmetric group of \( N \) and so, \( \alpha, \beta \) and \( \gamma \) are respectively, permutations of rows, columns and symbols of \( L \). The resulting square \( L^\Theta \) is also a Latin square and it is said to be isotopic to \( L \). If \( \gamma = \epsilon \), the identity map on \( N \), \( \Theta \) is called a principal isomorphism. An isomorphism which maps \( L \) to itself is an automorphism. \( (\epsilon, \epsilon, \epsilon) \) is called the trivial automorphism. The stabilizer subgroup of \( L \) in \( J_n \) is its automorphism group, \( U(L) = \{ \Theta \in J_n : L^\Theta = L \} \). Fixed \( \Theta \in J_n \), the set of all Latin squares \( L \) such that \( \Theta \in U(L) \) is denoted by \( LS(\Theta) \). The main class of \( L \) is the set of all Latin squares isotopic to some conjugate of \( L \).

Every Latin square of order \( n \) is equivalent to a 1-factorization of a bipartite graph \( K_{n,n} \) [3]. In particular, given a Latin square \( L \in LS(n) \) and fixed a set of \( n \) colors \( \{c_0, c_1, ..., c_{n-1}\} \), it can be defined a bipartite graph \( G = (V,E) \) with colored edges. To do it, \( V \) is partitioned into two subsets \( U \) and \( W \), where \( |U| = |W| = n \) and \( U \) and \( W \) represent, respectively, the rows and columns in \( L \). Besides, if \( (i, j, k) \in L \), then there will be an edge of color \( c_k \) joining the vertices \( i \in U \) and \( j \in W \). Each symbol of \( L \) determines therefore a monochromatic 1-factor of \( G \) and so, we obtain a 1-factorization \( \mathcal{F}(L) = [f_0, f_1, ..., f_{n-1}] \) of \( G \), where each 1-factor \( f_i \) is associated to the color \( c_i \). The reciprocal construction is also possible in a similar way and we can then construct a Latin square \( \mathcal{L}(F) \) associated to each 1-factorization \( F \) of \( K_{n,n} \). Indeed, \( \mathcal{F}(\mathcal{L}(F)) = F \) and \( \mathcal{L}(\mathcal{F}(L)) = L \). In particular, \( F \) and \( F' \) are two isomorphic 1-factorizations if and only if \( \mathcal{L}(F) \) and \( \mathcal{L}(F') \) are in the same main class.

![Figure 1: 1-factorization of \( K_{3,3} \) starting from a Latin square.](image)

Cardinalities of autotopism groups have been studied to obtain the number of Latin squares of order up to 11 [5], where computer programs incorporating two methods of approach to generation are used: the orderly approach method [2] and the canonical construction path method (CCPM) [4]. In particular, this last one allows to construct a Latin square one row block at a time, where a row block consists of the rows corresponding to a cycle of \( \alpha \). Besides, fixed an isomorphism
\( \Theta = (\alpha, \beta, \gamma) \in \mathcal{S}_n \), the CCPM has been also used [1] to study the number \( \Delta(\Theta) \) of Latin squares \( L \in LS(n) \) such that \( L \in LS(\Theta) \):

**Proposition 1.** Let \( \Theta = (\alpha, \beta, \gamma) \in \mathcal{S}_n \) be a non-trivial isotopism. If one of the permutations \( \alpha, \beta \) or \( \gamma \) is equal to \( \varepsilon \), then \( \Delta(\Theta) > 0 \) if and only if the other two permutations are both the composition of \( k \) cycles of length \( \frac{n}{k} \).

**Theorem 1.** Fixed \( k \in \mathbb{N} \), let \( \Theta = (\alpha, \beta, \varepsilon) \in \mathcal{S}_n \), where \( n > k \) is a multiple of \( k \), be such that \( \alpha \) and \( \beta \) are both the composition of \( k \) cycles of length \( \frac{n}{k} \). Then:

\[
\Delta(\Theta) = n! \cdot \binom{n}{k}^{k-1} \cdot \Omega(\Theta),
\]

where \( \Omega(\Theta) \) is 1, if \( k = 1 \), and the number of different ways in which the row blocks can be chosen in the CCPM, if \( k > 1 \).

Table 1: Values of \( \Omega(\Theta) \) and \( \Delta(\Theta) \) when \( 2 \leq n \leq 9 \).

The number \( \Delta(\Theta) \) is useful in Cryptography, when a Latin square \( L \) and a family \( \mathcal{F} \subseteq \mathcal{V}(L) \) are used to get a secret-sharing system, that is, a method of sharing a secret key \( K \), by giving \( n \) pieces of information called shares to \( n \) participants, in such a way that \( K \) can be reconstructed from certain authorized groups of shares and it cannot be done from unauthorized groups of them. Specifically, in this case, \( K = L \) and the shares are the triples of \( L \) and the isotopisms of \( \mathcal{F} \). In this way, the weight of information given by the latter is usually greater than that given by the former. On the contrary, the size of an isotopism is much larger than that of a triple. As this problem rises with \( n \), it is necessary to identify an isotopism with a share of a smaller size. In this paper we study one possibility in this sense, when \( \Theta \) is a principal isotopism such that the number \( \Delta_R(\Theta) \) of reduced
Latin squares having $\Theta$ as an autotopism is positive. In this way, we study the set of 1-factorizations associated to these reduced Latin squares and we identify $\Theta$ with a graph $\mathcal{S}_\Theta$ of smallest size with colored vertices and edges.

2. The canonical construction path method.

Fixed $n \in \mathbb{N}$ and $\Theta \in \mathcal{S}_n$, $\Delta_\mathcal{S}(\Theta)$ will denote the cardinal of the set $RLS(\Theta)$ of reduced Latin squares of order $n$ such that $\Theta$ is an autotopism of all of them. In this paper, we are interested in the value of $\Delta_\mathcal{S}(\Theta)$ if $\Theta$ is a non-trivial principal autotopism. From Proposition 1, it suffices to study those autotopisms $\Theta = (\alpha, \beta, \varepsilon)$, such that $\alpha$ and $\beta$ have all their cycles of the same length and without fixed points:

$$\alpha = C_{\alpha}^0 \circ C_{\alpha}^1 \circ \ldots \circ C_{\alpha}^{k-1}, \quad \beta = C_{\beta}^0 \circ C_{\beta}^1 \circ \ldots \circ C_{\beta}^{k-1},$$

where $C_{\alpha}^\delta = (c_{i,1}^\delta, c_{i,2}^\delta, \ldots, c_{i,k-1}^\delta)$ is a cycle of length $\frac{n}{k}$ for all $\delta \in \{\alpha, \beta\}$ and $i \in \{0, 1, \ldots, k-1\}$, being $c_{i,j}^\delta \in \mathbb{N}$. For all $j \in \{0, 1, \ldots, k-1\}$. Besides, it must be $c_{i,j}^\delta \neq c_{k,j}^\delta$ for all $(i, j) \neq (k, l)$. From now on, we will suppose that $c_{0,0}^\alpha = c_{0,0}^\beta = 0$.

**Lemma 1.** If $C_{\alpha}^0 \neq (C_{\alpha}^0)^{-1}$, then $\Delta_\mathcal{S}(\Theta) = 0$.

Now, if we want to find a reduced Latin square $L = (l_{ij}) \in RLS(\Theta)$, we will use the CCPM. So, we define the following subrectangles of $L$:

$$R_{ij} = \left\{ (c_{ij}^\alpha, c_{ij}^\beta, l_{ij}^\alpha, l_{ij}^\beta) : s, t \in \{0, 1, \ldots, \frac{n}{k} - 1\} \right\},$$

for all $i, j \in \{0, 1, \ldots, k-1\}$. When all these subrectangles are known, then $L$ is determined. Due to it, it is useful to define also the following sets:

$$S_{ij} = \{ l_{ij} : (s, t, l_{ij}) \in R_{ij} \}, \text{ for all } i, j \in \{0, 1, \ldots, k-1\}.$$

**Lemma 2.** The following asserts are verified:

a) $|S_{ij}| = \frac{n}{k}$, for all $i, j \in \{0, 1, \ldots, k-1\}$.

b) $\bigcup_{j=0}^{k-1} S_{ij} = \mathbb{N}$, for all $j \in \{0, 1, \ldots, k-1\}$.

c) $\bigcup_{i=0}^{k-1} S_{ij} = \mathbb{N}$, for all $i \in \{0, 1, \ldots, k-1\}$.

d) If $(i, j) \neq (s, t)$, then $S_{ij} \cap S_{st} = \emptyset$ whenever $i = s$ or $j = t$.

e) $S_{ij} = S_{ij}^0 = \{ i : \frac{n}{k}, i : \frac{n}{k} + 1, \ldots, (i+1) \cdot \frac{n}{k} - 1 \}, \text{ for all } i \in \{0, 1, \ldots, k-1\}$.
f) If \( l_{\alpha} \) is known, being \((s,t,l_{\alpha}) \in R^{i,j}\), then the \( \frac{n}{k} \) cells \((u,v,l_{uv})\) of \( R^{i,j}\) such that \( l_{uv} = l_{\alpha} \) are known.

\[ g) \text{ If } S^{i,j} \text{ is known then } R^{i,j} \text{ can be chosen of } \frac{n}{k}! \text{ ways.} \]

As a consequence, the subrectangles \( R^{i,0} \) and \( R^{0,j} \) are known for all \( i, j \in \{0,1,...,k-1\} \) and we can define the following partial Latin square:

\[ P_{\Theta} = \bigcup_{i} R^{i,0} \cup \bigcup_{j} R^{0,j} \in PLS(n), \]

which is common to all Latin squares of \( RLS(\Theta) \). Indeed, to determine \( L \), we only must fix the \((k-1)^2\) subrectangles \( R^{i,j}\) with \( i \neq 0 \neq j \).

**Theorem 2.** \( \Delta_R(\Theta) = \left( \frac{k}{\varphi(k)} \right)^{(k-1)^2} \Omega_R(\Theta) \), where \( \Omega_R(\Theta) \) denotes the number of different ways in which the elements of all sets \( S^{i,j} \) can be chosen.

In particular, the cases \( k \in \{1,2,3,4\} \) of Table 1 are easily computable by following the CCPM. The following result is then verified:

**Theorem 3.** Fixed \( k \in \{1,2,3,4\} \), let \( \Theta = (\alpha, \beta, \varepsilon) \in \mathcal{A}_n \), where \( n > k \) is a multiple of \( k \), be such that \( \alpha \) and \( \beta \) are both the composition of two cycles of length \( \frac{n}{k} \), being \( C_0^\Theta = (C_0^\Theta)^{-1} \). Then:

\[ a) \text{ If } k \neq 4: \quad \Omega_R(\Theta) = 1, \quad \Delta_R(\Theta) = \begin{cases} 1, & \text{if } k = 1, \\ \frac{n}{k}!, & \text{if } k = 2, \\ \left( \frac{n}{k} \right)^4, & \text{if } k = 3. \end{cases} \]

\[ b) \text{ If } k = 4: \quad \Omega_R(\Theta) = \sum_{a,b,c,d} \left( \frac{a}{b} \right) \left( \frac{a}{a+b} \right) \left( \frac{c}{a+b} \right) \left( \frac{\frac{n}{k} - a}{c} \right) \left( \frac{\frac{n}{k} + a+b}{\frac{3}{4} - c} \right) \left( \frac{\frac{n}{k} - c - d}{e} \right) \left( \frac{d}{d+e} \right). \]

3. 1-factorizations associated to principal autotopisms of reduced Latin squares

Let \( \Theta \in \mathcal{A}_n \) such that \( \Delta_R(\Theta) > 0 \). By following the CCPM described in the previous section, we can define the set \( RLS(\Theta) \), starting from the subrectangles \( R^{i,j} \) associated to \( \Theta \). So, we can define the set \( \mathcal{F}(RLS(\Theta)) = \{ \mathcal{F}(L) : L \in RLS(\Theta) \} \). As we have previously observed, all Latin squares of \( RLS(\Theta) \) have the partial Latin square \( P_{\Theta} \) in common. Due to it, it can be useful to extend to partial Latin

* Being \( C_0^R = (C_0^R)^{-1} \). Otherwise, \( \Delta_R(\Theta) = 0 \).

Table 2: Values of \( \Omega_R(\Theta) \) and \( \Delta_R(\Theta) \) when \( 2 \leq n \leq 9 \).

squares the above algorithm which allows to construct a 1-factorization starting from a Latin square. Indeed, it is enough to ignore in the mentioned algorithm those edges corresponding to triples \((i, j, \emptyset)\). In this way, we will obtain a subgraph of \( K_{n,n} \) with colored edges. Fixed \( P \in \text{PLS}(n) \), we will denote this subgraph as \( \mathcal{F}(P) \).

**Proposition 2.** The following asserts are verified:

a) \(|\mathcal{F}(\text{RLS}(\Theta))| = \Delta_R(\Theta)\).

b) \(\bigcap_{F \in \mathcal{F}(\text{RLS}(\Theta))} F = \mathcal{F}(P_\emptyset)\).

Let us see an example:

**Example 1.** Let \( N = \{0, 1, 2, 3\} \). The unique possible isotopisms verifying the conditions of Theorem 3 for \( k = 2 \) are:

\[
\Theta_1 = ((01)(23), (01)(23), e); \quad \Theta_2 = ((02)(13), (02)(13), e);
\]

\[
\Theta_3 = ((03)(12), (03)(12), e).
\]

Now, the graphs \( \mathcal{F}(P_{\emptyset}) \) related to each \( \Theta_i \) are shown in Table 3. Indeed, it can be proved that \( \mathcal{F}(P_{\emptyset}) \), \( \mathcal{F}(P_{\Theta_1}) \) and \( \mathcal{F}(P_{\Theta_1}) \) are isomorphic 1-factorizations.

However, we can find another graph related to \( \Theta \) with smaller size than \( \mathcal{F}(P_{\emptyset}) \). To do it, it is enough to observe that the first row and column of \( P_{\emptyset} \) are fixed with the elements of \( N = \{0, 1, \ldots, n-1\} \), which determine the colours of \( \mathcal{F}(P_{\emptyset}) \). So, we can follow this algorithm:

**Algorithm 1.**

i) Fixed \( i \neq 0 \), we colour each pair of vertex \( u_i \) and \( w_i \) with the color \( c_i \).

ii) We eliminate the vertices \( u_0 \in U \), and \( w_0 \in W \) and their incident edges.

The resulting graph has therefore colored vertices and edges and determines \( \Theta \). This graph will be denoted by \( \mathcal{F}_{\emptyset} \) and it will be called the **graph related to \( \Theta \)**. In Table 4, we can see the case of Example 1.

$\mathcal{F}(P_{\Theta_1})$

**Table 3:** Graphs $\mathcal{F}(P_{\Theta_1})$ related to $\Theta_1$.

### 4. Final remarks

The graph $\mathcal{G}_\Theta$ allows to recover the isotopism $\Theta$. In this way, we can consider a set of vertices and edges of $\mathcal{G}_\Theta$ as shares in a secret-sharing system. So, the size of these shares would be smaller than that of $\Theta$. It would allow to increase the number of participants in such a system and to adjust the weight of information of the used shares. Anyway, it is possible to find a graph of smaller size than $\mathcal{G}_\Theta$. To do it, let us observe that, fixed a vertex in this graph, its color must be different from those of its incident edges. Furthermore, these last ones have also different colors between themselves. So, keeping in mind these properties, we can eliminate some vertices and edges of $\mathcal{G}_\Theta$ and we can therefore obtain a graph of the smallest size allowing to recover $\Theta$. It would be therefore necessary an analogous study to that of forcing sets of a 1-factorization.
